EXECUTIVE SUMMARY

Richard Grubb & Associates, Inc. (RGA) completed Phase II archaeological evaluation of the Polk Tenant Site (CRS N05221, 7NC-F-111) within the proposed U.S. Route 301 Mainline Section 3, in St. George's and Appoquinimink Hundreds and the Town of Middletown, New Castle County, Delaware. A Phase II archaeological evaluation was completed as part of the implementation of a Memorandum of Agreement (MOA) developed between the Federal Highway Administration (FHWA), the Delaware Department of Transportation (DelDOT), the Delaware State Historic Preservation Office (DESHPO), and the Maryland Historical Trust (MHT), executed in November and December of 2007.

The Polk Tenant Site was found eligible for the National Register of Historic Places, but was not considered a good candidate for traditional data recovery excavations. One of the features found at the site was a brick-lined well. In lieu of traditional data recovery at the site, DelDOT and the Delaware State Historic Preservation Office agreed on an alternative mitigation involving preparation of a technical report of the evaluation investigation and a study synthesizing current data on historical wells across the state.

In addition to writing up the site archaeology, Versar conducted a special study on wells in Delaware. Several of the sites along the Route 301 corridor had very well preserved wells, and while wells have been excavated at many sites across the state, there is still a lot we do not know about these important features. Creating a synthesis of this feature type from across the state provides an opportunity to expand what we know about how wells were built and used.

Versar archaeologists and historians gathered information on 58 previously excavated wells from across Delaware. Data collected included the shape of wells that have been found, the methods and materials used to construct them, and where the wells occur relative to houses, barns or other structures. Versar also examined the methods archaeologists used to excavate these wells. This report summarizes what is known about wells in Delaware and creates a research tool that other archaeologists will be able to use to see how wells they find compare to what has been documented previously.

Analysis of wells excavated in Delaware reveals a number of interesting patterns about these simple but vital features of the landscape. Wells in Delaware are nearly always very shallow (most less than 15 feet deep) and located very near a structure, sometimes the main occupation building of the site, sometimes an outbuilding. They are made with a variety of materials and construction techniques. There are wells made from brick, stone and stone and brick together. Wood-lined wells are mostly rectangular frame in construction, but can also be circular, or made with stacked barrels, and in one case, stacked hollow logs. Most of these technologies appear to have been used throughout most of Delaware's history, though the range of wood-lined wells (last quarter 17th century to 3rd quarter 19th century) is a little earlier than brick-lined wells (2nd quarter 18th

century to the present). Brick and wood wells are found in each of the three counties of Delaware, but stone-lined wells are found only in the northern part of New Castle County, the only part of the state in the Piedmont where building stone is common.

Analysis of wells excavated to date also shows some gaps in the existing literature. Most of the wells excavated so far have been from the northern part of the state: there are few excavated wells from Sussex County. Well depth is inconsistently recorded; archaeological excavation was frequently abandoned once the water table was hit. In addition to leaving the bottom depth of these wells unclear, it also makes it harder to determine the date at which the well was abandoned.

Although the overall problems with sample size and recording inconsistencies provide reasons to record in detail any historic well found on an archaeological site, it is possible to suggest some priorities. Evaluation of the information potential of a well should put emphasis on those with a good historical context. Wells located in sites with overall high physical integrity have more information potential than isolated wells. Wells from sites with evidence for the location of nearby structures, as well as the potential for meaningful soil chemistry will be able to better illustrate how the well feature functioned within the overall site, and potentially how safe the water from that well might have been. Conversely, wells that are not accompanied by other well-preserved features with clear functions, or that are on sites with little or no documentation, or that cannot be reliably dated, are not necessarily valuable archaeologically. If a site lacks good documentation or well-preserved features other than a well, the presence of even an intact well is probably not enough by itself to make the site eligible, or warrant the expense of excavating the well feature.

1.0 PROJECT BACKGROUND

Richard Grubb & Associates, Inc. (RGA) completed Phase II archaeological evaluation of the Polk Tenant Site (CRS N05221, 7NC-F-111) within the proposed U.S. Route 301 Mainline Section 3, in St. George's and Appoquinimink Hundreds and the Town of Middletown, New Castle County, Delaware. U.S. Route 301 is a proposed four-lane toll highway that will extend approximately 17.5 miles from near the Maryland-Delaware border to State Route (SR) 1 south of the SR 1 Bridge over the Chesapeake and Delaware Canal. The proposed U.S. Route 301 Mainline Section 3 extends north from near the Maryland/Delaware State Line in Maryland to north of Levels Road near Middletown, Delaware, a distance of approximately 4.5 miles. The Polk Tenant Site was identified during Phase IB archaeological survey of the proposed corridor conducted in 2009 and 2010 (RGA 2009, 2011a).

A Phase II archaeological evaluation was completed as part of the implementation of a Memorandum of Agreement (MOA) developed between the Federal Highway Administration (FHWA), the Delaware Department of Transportation (DelDOT), the Delaware State Historic Preservation Office (DESHPO), and the Maryland Historical Trust (MHT), executed in November and December of 2007.

The Polk Tenant Site was identified in the northern portion of the U.S. Route 301 Mainline Section 3 (Figures 1-1 and 1-2). The site was characterized by clusters of nineteenth-century artifacts located on both sides of a farm lane near the nineteenth-century Polk House, a National Register-eligible property formally referred to as the C. Polk House Estate (CRS N05221). As its name suggests, the Polk Tenant Site is considered a tenant house (RGA 2011a).

One of the features found at the site was a brick-lined well. In lieu of traditional data recovery at the site, DelDOT and the Delaware State Historic Preservation Office agreed on an alternative mitigation involving preparation of a technical report of the evaluation investigation and a study synthesizing current data on historical wells across the state.

In addition to writing up the site archaeology, Versar conducted a special study on wells in Delaware. Several of the sites along the Route 301 corridor had very well preserved wells, and while wells have been excavated at many sites across the state, there is still a lot we do not know about these important features. Creating a synthesis of this feature type from across the state will provide an opportunity to expand what we know about how wells were built and used.

Versar archaeologists and historians gathered information on previously excavated wells from across Delaware. Some of the information collected included the shape of wells that have been found, the methods and materials used to construct them, and where the wells occur relative to houses, barns or other structures. We also examined the methods archaeologists use to excavate wells. This report summarizes what is known about wells

in Delaware and creates a research tool that other archaeologists will be able to use to see how wells they find compare to what has been recorded previously.

2.0 INTRODUCTION

2.1 Definition of the Problem

Wells are potentially valuable archaeological features, and fairly common on historical sites. More than 50 have been excavated at least partially in Delaware, including six along the Route 301 extension corridor, but there has never been a synthesis of the data or lessons learned from excavating these features. The present study is confined to wells, as opposed to all types of shaft features, partly to limit the scope of this particular investigation, and also because the construction and use of wells represents a cultural phenomenon distinct from cisterns and privies. Developing a synthesis of data collected about wells as archaeological features will facilitate future comparative analysis of well features. It will also allow us to assess what has been learned thus far, identify gaps in the archaeological record on wells, and support the development of management recommendations for the future excavation of these important features.

2.2 Hydrology

Water is critical to life—an obvious statement but one with important implications for archaeology. Water is found throughout the earth’s surface in flowing streams, in springs, or in lakes and oceans. People have settled and lived near water from time immemorial. When looking for prehistoric Indian sites, one of the first things archaeologists look for is water, since settlements are usually found within easy distance of surface water. But water also occurs underground. European colonists took advantage of this source of water by digging wells. They could seek water below ground, allowing them to settle in locations that were sometimes far away from free-flowing streams.

The distribution of water on the planet is governed by what geographers refer to as the hydrologic cycle. This cycle is actually a complex series of physical processes that describes the movement of water in all its forms on the earth, from the formation of clouds to the rains that drain into rivers, lakes and the oceans. Researchers describe the cycle in terms of processes such as evaporation, condensation, precipitation, run-off, percolation and storage (NOOAA/NWRFC nd). Bernard Palissy, an early French scientist and land surveyor, who may be better known for his efforts in a different field entirely—his attempts as a potter to reproduce fine Chinese porcelain—was the first modern theorist to correctly describe the hydrologic cycle. Here is part of what he said in the late 1500s:

“Rain water that falls in the winter goes up in summer, to come again in winter...And these waters, falling on these mountains through the ground and cracks, always descend and do not stop until they find some region blocked by stones or rock very close set and condensed....they flow out as fountains or brooks or rivers according to the size of the opening and receptacles...” (Discourse Admirables, Palissy 1580, in International School of Well Drilling (ISWD) 2004:5).

Palissy also correctly deduced the origin of artesian pressure in wells and the fact that wells near rivers could be connected to the rivers through “underground veins” (Palissy 1580, in ISWD 2004:5).

Water wells are structures designed to provide access to water that lies below the surface in these “underground veins,” whether the veins be streams or aquifers (water trapped in deposits of sand, gravel or rock). Wells represent a reliable source of water, being less subject to the variations in weather that may affect surface water such as rivers, streams or even springs. Wells are part of an ancient technology that has been used in some parts of the world for millennia to tap subsurface water supplies. Wells were dug in Eastern Germany, for example, as many as 7,500 years ago in the Early Neolithic. These wells showed evidence of some of the earliest recorded wooden architecture in the world. Notched and pegged wooden cribbing was used to line the wells—the waterlogged wood has been preserved in anaerobic conditions (Tegel et al. 2012). The oldest recorded wells so far discovered are from western Cyprus, where a series of six wells were excavated between 9,000 to 10,500 years ago through hard, calcareous or chalky sediment to reach an underground stream that flowed atop bedrock (Peltenburg et al. 2001; Peltenburg 2003).

2.3 History of Wells

Early colonial period wells in eastern North America were often shallow, tapping aquifers that were relatively close to ground surface. These aquifers, sometimes referred to as perched or unconfined aquifers, were recharged by water directly from the contemporary ground surface and so were easily contaminated. Shallow wells with tainted water were often the source of fevers and more serious diseases. Deep wells may reach what are called confined aquifers, bodies of water that are located between impermeable geological layers such as rock or clay. Water in these cases may be very old and is usually not subject to surface contaminants. Confined aquifers often occur under pressure, in which case the wells tapping them are referred to as artesian.

When we think of a well we frequently picture a wide, brick-lined structure. To be functional, however, a well need only be large enough in diameter to allow water to be drawn from it. Driven wells, in which an iron pipe was pushed or driven into the ground to reach the aquifer, began to appear in some parts of the country by the mid-19th century (Thomas 1869:220). The pipe that was used was pointed and had holes drilled in it to allow water to be drawn in. Driven wells were best suited for shallow, sandy or gravelly aquifers within 30 feet of the ground surface, however, and were not common (Bowman 1911; Dick 1968). Modern wells that are mechanically drilled are, like driven wells, only the diameter of the pipe leading down to the aquifer. Historically, early techniques for drilling water wells in this country were developed as part of the salt mining industry around the beginning of the 19th century. The wells were dug to collect the salt found in brine water, which was used in preserving foods in the days before widespread refrigeration. The drilling process may be more rightly referred to as percussion drilling: a heavy chisel-like tool was dropped down the narrow shaft of the drill to crush hard rock or sediment. A by-product encountered in some of these wells in Pennsylvania was at

first considered undesirable, but eventually became a profitable commodity: "...sometimes a good well would be fouled with the intrusion of unsought and unwanted oil. The rainbow sheen and pungent smell of oil was bad news to brine drillers" (AOGHS 2010).

Many domestic water wells in Delaware would have been hand dug, however, often through relatively soft sandy soils. They represented a substantial effort to construct. Being excavated by hand, a well would have been large enough in diameter for a person to enter in order to dig to the aquifer. The well shaft would be dug until incoming water at the base exceeded the digger's bailing rate (Waller 1994:14). Some form of lining was usually required to support the shaft during and after excavation and to keep debris out of the water. Unlined shafts would be unworkable and impractical; if found archaeologically they probably represent abandoned shafts from which the lining has either collapsed or been robbed for use elsewhere.

Some of the earliest wells were wood-lined; barrels were often used for this purpose since they were already fashioned in a usable size and shape. Barrels were used to line the wells excavated at 16th-century colonial Spanish Santa Elena, in South Carolina (South 1991). Stone and brick were also commonly used as liners, sometimes in combination with wood in some form. A wide wooden ring, called a curb, was often used at the bottom of the well excavation as a base for the lining, to help keep it level and from sinking into the soft, waterlogged sediments. In cases where the ground was very soft, the initially excavated shaft might be made larger than the desired well diameter. The excavation would be cribbed, like a caisson, providing a clear space within which to work. The well lining would be constructed within the cribbing and the intervening space eventually backfilled (Wigginton 1977). Regardless of the type of lining or how it was constructed, its purpose was to support the shaft. It was not watertight, however, but was designed to allow water from the underground stream or aquifer to flow into the base of the well shaft providing direct access to the water from the surface.

2.4 Well Technology

Wells are, of course, primarily used to extract groundwater. Once a well was dug, there was still the matter of getting water out of it regularly and conveniently. Many shallow wells were pumpless. Water could be lifted directly by a combination of bucket and rope, often aided by a pulley mechanism (Ewbank 1842). This technique is practical to depths of as much as 100 m, but would be a chore in wells more than 45-50 m deep. For this reason the simple bucket-and-rope was not typically used for deep wells (Olley 2008). A pulley could be given additional mechanical advantage by the addition of a small winch or windlass (Ewbank 1842).

Another mechanism used for drawing water from shallow wells was a well sweep (or in England a swape). Called a shadouf in the Middle East, where the technique may have originated, the sweep consisted of a long wooden arm with a rope and bucket attached and a counterweight at the opposite end (Ewbank 1842). Sweeps were common in

Delaware, but were replaced in the late 19th century with water pumps (Lanier and Herman 1997).

Pumps are more complex mechanisms than ropes, pulleys and winches, but they can extract water from a well with less physical effort. A pump employs the physical properties of water to lift it up the well shaft to the surface. Water is a substance that cannot effectively be compressed—it cannot be forced into a smaller volume. It can, therefore, be pushed or displaced. Pumps use this characteristic to their advantage, operating on the principles of lift and suction. A pipe, sometimes called a tube or a stock, is extended to the water at the base of the well. The water is then either pushed up by a piston plunger, or drawn up by the suction created as the piston is pulled up the pipe. Pumps also take advantage of leverage in the way the handle is set up, and thus they require less physical effort overall than a simple rope and pulley. Use of a pump also allows the well to be covered or even sealed, lessening the risk of direct contamination down the open shaft. Pumps may, however, be relatively complex, requiring a certain level of basic technical knowledge for their construction, maintenance and repair.

Most simple pumps used in wells in Delaware worked by drawing water up the pipe with a piston and pushing it out the top through a spout. To do this, the pumps used two valves, one at the foot of the pump and one on the piston. Valves are mechanisms that control the flow of water, in this case allowing it to move in only one direction. The valves used in these simple pumps were a basic form known as a check valve. They consisted of a flap of heavy but supple leather that allowed water to pass only one way—upward into the pipe. The valve would be held closed by water pressure, keeping the water from falling back down the tube. As the pump drew the piston up through the pump stock or pipe, the valve on the piston would remain closed. The piston was tightly fitted within the pump stock and thus it created a vacuum in the pipe as it ascended. Water was drawn up behind the piston—in fact this was in response to atmospheric pressure pressing on the underground water.

In a wooden pump, the pipe or pump stock was made from the bole of a straight tree, sometimes in two or three sections or stocks, depending on the depth of the well and the sizes of the trees available. Amos Long, in his extensive description of the workings of a traditional Pennsylvania farm (1972) recommended oak for the stocks. Elm was also commonly used, since it was durable when wet (Oertling 1984). At the Whitten Road Site (Shaffer et al. 1988), the stocks were made from sweet gum. Long straight tree boles were sought. The stocks were bored to the proper diameter with an auger using successively larger bits. The ends were tapered and reamed for a watertight and airtight fit.

Water entered through holes drilled through the stock near the base. The force of the water being drawn upward opened the foot valve at the bottom of the stock. On the down stroke, the check valve on the piston opened allowing water to pass through as the piston descended, while the weight of the water in the pump stock closed the check valve on the foot of the tube, keeping it from draining out. On the next up stroke, the piston valve again closed and the foot valve opened. When water was drawn high enough to reach the

piston, the piston would push the water above it up the tube and out the spout, while at the same time drawing water from below as it continued to create a vacuum while traveling upward.

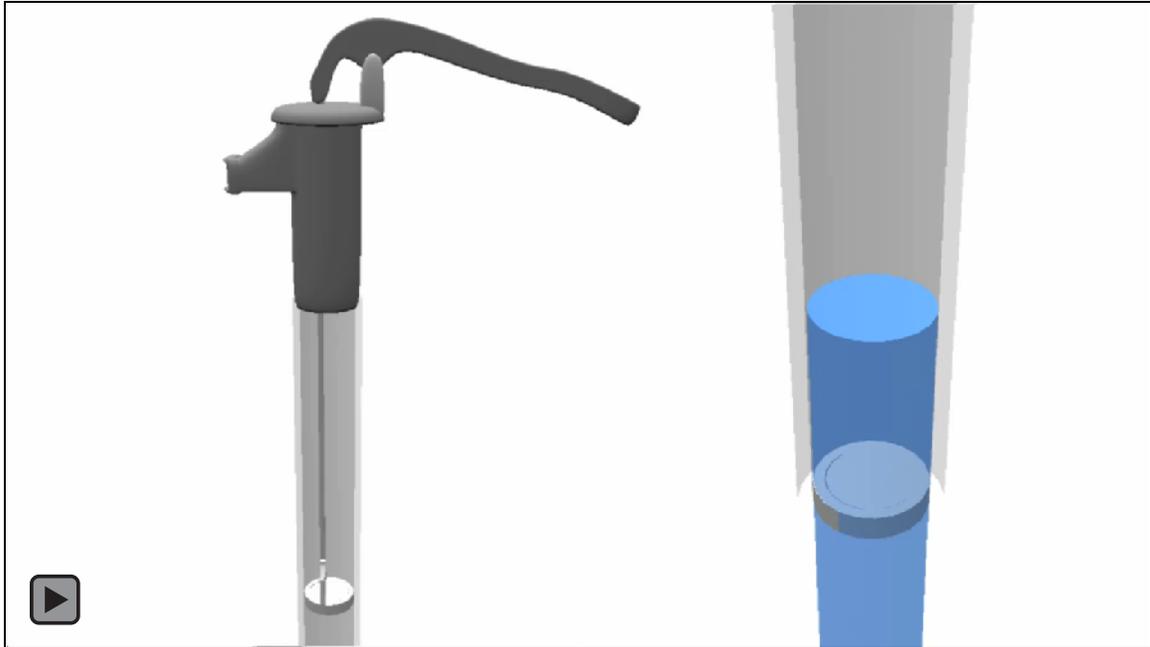

Figure 2.1: Animation of example suction pump. Click play to run animation.

The base of the pump stock was closed with a wooden plug to keep out sediment. The holes at the base of the stock that let water in were located high enough from the bottom of the well to keep sediment from being drawn up with the water. In some pumps, such as the one documented at Whitten Road, the base of the pump stock was surrounded by a box containing sand to further filter the incoming water.

Pumps operate on the principles of suction and lift. Table 2.1 lists types of pumps and their physical limitations. Suction is the vertical distance between the water and the pump, while lift is the vertical distance between the pump and the top of the well. The depth from which a hand pump can lift water is limited by atmospheric pressure to an operating depth of less than 7 meters. Within this range, the lifting capacity is generally governed by the size of the pump (a small diameter pipe can achieve more lift than a large diameter pipe) and the strength of the operator.

Some bilge pump tubes were essentially long, narrow boxes constructed of planks bound with hoops, a type apparently used by the U.S. Navy in the early 19th century (Oertling 1984:22). Some of the descriptions of pump stocks from Delaware wells refer to “square wooden” structures (e.g., Thomas Williams Site in Catts and Custer 1990:123). At the Armstrong Rogers Site, the dairy well pump was formed from a single hollowed log. The 7.5 foot long surviving portion weighed nearly 400 pounds.

Table 2.1: Types of Well Pumps	
Types:	Limitations
Suction and lift hand pumps	about 7 meter depth limit (23 feet).
Direct action – water pulled up directly by a pumping rod. Easy to install and maintain,	physical limit of about 15 m depth (50 feet).
Deep wells –	hand pumps for deep wells entail some form of mechanical assistance, such as a lever or flywheel.

The base of the tube differs between bilge pump and well. A bilge pump was designed to remove water from the bilge or bottom of a ship and had inlets or limber holes cut at the bottom of the tube where it butted against the hull planks. A metal screen or sieve was often used to keep debris from being pulled up and clogging the pump valves. In contrast, wells tapped groundwater that was usually at the base of a sediment-filled excavation. The pump stock had intake holes drilled some distance above the bottom of the well to keep sediment from being drawn up with the water, a little over a foot above in the case of the Armstrong Rogers pump (Figure 2.2).

Figure 2.2: Intake hole on the pump stock from the Armstrong Rogers House site, Delaware. Click to launch 3D model view.

A narrow construction shaft was associated with Feature 17, a box-lined well at the Whitten Road site (Shaffer et al. 1988:113). The remains of a wooden pump stock were documented at its base. The stock was surrounded by inner cribbing and the space between the well box and inner cribbing was packed with sand, presumed to be a filtration system. Shaffer et al. (1988:127) reported two other locations with the remains of pump stocks, one in Wilmington and the other in Landenberg, Pennsylvania.

As archaeological features

Unless badly disturbed, most wells are easily recognizable by their typically round shape and regular size—usually about 4-6 feet in diameter. The lining is often preserved and easily identified, particularly if it is stone or brick. Wells are also for the most part easy to distinguish from cisterns. The term cistern comes from Latin (*cista*) and Greek (*kiste*) words meaning box. A cistern is a wide, covered reservoir for holding surface water, in contrast to a well, which is a narrow shaft designed to gain access to underground water. A cistern is typically an above-ground feature and considerably wider and shallower than a well. The structure is sealed (consisting, for example, of mortared or parged masonry) in order to contain water, whereas a well is designed to let water pass through (consisting of dry-laid masonry). There is also a marked difference in water quality between the two types of feature—cisterns often stored rain water, which was soft, while well water typically contained minerals that made it hard.

The above-ground features of wells—pumps, sweeps, caps, shelters—are seldom preserved intact archaeologically. Occasionally, there are below-ground remains of associated features. Our sample of 58 excavated wells included 14 that had postholes or brick foundations nearby indicating that there had been some kind of a structure covering the well at one time. In addition to covering a well or housing a pump, such structures might have facilitated secondary use of a well as a form of cold storage. Milk and cream or other perishable items would be lowered in a bucket to a level just above the surface of the water where the air was cool (Dick 1968). Care had to be taken not to spill the contents of the bucket while lowering or raising it, however, lest the well be contaminated. Excavated wells also sometimes include remnants of internal pumpstocks (as did 4 wells in our sample) as well as occasional lining materials such as lime or clay. These details can help date well features and elaborate what is known about the well technology in use.

Wells can tell us about how people lived, how they organized the space in which they lived, their technologies—both those that were available to them and those they actually used. More than one contemporary well, for example, might imply a certain degree of affluence or might indicate the function of the site, one well being for domestic use, the other specifically for agriculture or animal husbandry.

The location of a well relative to other yard features could be critical to its safe and effective functioning. Bacterial contamination and other pollution effects might result from proximity to privies or from septic-tank effluent or barnyard run-off (Waller 1994:22). Thus the placement of a well on an archaeological site may provide information about the contemporaneity of features—a well located next to a privy, for example, might suggest they were from different occupations or periods of site use.

Wells represent a further interest to archaeologists in that when they were exhausted (dry) and abandoned, they usually became convenient receptacles for trash disposal. One regional researcher has observed that:

“It sometimes surprises people to learn that wells, which required so much effort to dig, were commonly used as trash pits. In the days before steel

pipe and concrete culverts, however, wells were never expected to last forever, and wood-lined wells had particularly short life expectancies. The lining at the bottom rotted—even brick, which was not nearly as hard in the eighteenth century as it is today, rotted when it lay in the water—the bottom of the well started to silt up or even collapse, and after a certain point it was cheaper and safer to dig a new well than to keep trying to repair the old one. An abandoned well was both a safety hazard and a perfect place to throw trash, so most abandoned wells were soon filled” (Bedell et al. 1999:44).

And since archaeologists study the material remains of past cultures—which is another way of saying that they deal in other people’s trash—wells as trash pits are often of great interest. A wide variety of things get thrown down an old well, probably leading at least in part to the old saying “out of sight out of mind.” Occasionally we get lucky and the bottom of a well is not dry or has not stayed dry for long after it was abandoned. Waterlogged sediments tend to be anaerobic—without oxygen. Oxygen sustains bacteria, and bacteria are a major factor in the decomposition of organic material. So, preserved at the base of a wet well we sometimes find artifacts made from materials that usually deteriorate quickly, such as leather (shoes, belts, book bindings), bone (knife handles, brushes, decorative items, the remains of meals), or even cloth. A famous example was one of the wells from the early English settlement at Jamestown, Virginia, that contained a halberd with part of the wooden staff intact. A halberd was a pole axe, a weapon that by the early 17th century was generally only used for ceremonial purposes. This example bore two griffin heads from the De La Warr family crest on its blade, and thus probably belonged to Sir Thomas West, the Baron De La Warr, who arrived at Jamestown on June 10, 1610. Also, found were butchered horse bones, indicating the coming time of starvation for the English colonists as they began eating their domestic stock (Historic Jamestown nd; Popular Archaeology 2011).

If a well remained open during successive site occupations, the debris in it may be layered. Careful excavation of the well’s contents may show us how the various people living at the site changed through time, how their diet and consumption patterns varied, for example. The Narbonne House well, in Salem, Massachusetts, was filled in over the course of a short period of time, based on the dates of the artifacts recovered from it—the span was not much before 1865 and not after late-1869 (Moran et al. 1982:242). Mended artifacts were found in various levels, but the mends generally occurred within 6-18 inches of each other vertically. This finding suggested that overall, the deposits were not stratified, which in turn implied rapid filling of the well shaft. Many mends and the comparative absence of extraneous (unmended) sherds were interpreted as evidence that the fill included little yard debris. Dates from the artifacts aligned with archival evidence—municipal water service began in Salem in 1869, following which the well would not have been needed, corresponding with the end of the artifact date range.

“It’s clear that archaeologists who dig wells are more often preoccupied with contents than with containers” (White 1994:46). Nevertheless, wells in and of themselves can be informative. In a paper published in the mid-1990s, White enumerated a series of

attributes by which he sought to characterize wells as built features, regardless of their archaeological contents. The characteristics he identified included quantitative variables such as the diameter of the shaft, wall thickness, depth, and distances to other features or structures on site, and several nominal or qualitative variables involving such things as construction materials and workmanship. Through examination of these characteristics, he argued that the researcher can determine function—distinguishing between wells and cisterns, for example; type—domestic versus stock or agricultural wells, by the workmanship; or time period—variations in depth, material, or workmanship (White 1994:44). He further noted that some of the variables can be used as a basis for inferences about the occupants of the property—affluence, social standing—and even to distinguish the work of individual well diggers.

White noted which attributes are most often documented archaeologically based on reports from 26 sites on which wells were recorded (he was not specific as to the geographic locations). The inside diameter of the well shaft and the construction materials were the most consistently recorded variables. Depth was recorded if the well was fully exposed, and location and distance to structures could usually be obtained from site maps. The other attributes, which require varying amounts of qualitative assessment, were inconsistently reported.

White's assessment is one of the only published works on wells that concerns itself with their physical characteristics as archaeological features rather than focusing on their contents. It points up the difficulty in surveying the literature on wells: i.e., there is little if any consistency in what is recorded. This situation is partly the fault of the individual researchers, who typically opt for the obvious or easy analysis—the artifacts in the fill. And in fairness, the artifact data are often voluminous, requiring a substantial amount of time and resources to analyze, not leaving much for the features themselves. But the inconsistencies in documentation are also related to practical difficulties in recording wells in the field. They are in many ways as difficult and dangerous to investigate archaeologically as they were to excavate originally. Most wells tend to be excavated the same way archaeologically for reasons of safety and economy—the uppermost surviving portions, usually to a depth of 4-6 feet, are hand excavated, the rest sampled with a backhoe. The part that is most carefully excavated is often the least interesting from the perspective of structural and construction characteristics, since the upper part is the most likely to be disturbed and thus to be a better record of what has happened to the feature since the site was abandoned than of its original makeup. As an example, the wells at the McKean/Cochran Farm Site, in New Castle County, were as fully documented as most archaeological examples in Delaware:

“The excavation of the wells on the site was not entirely successful. The technique employed was to excavate the upper 4 to 5 feet of the well by hand, without shoring. In the case of Feature 29, the earlier well, substantial numbers of artifacts were still being recovered at that depth, so a backhoe was employed to enlarge the excavation in order to continue it to a greater depth. By a depth of 6 feet the fill had become sterile, and augering showed that it was still sterile at 12 feet, so excavation of the

well was abandoned. However, 12 feet was probably nowhere near the bottom of the well...” (Bedell et al. 1999:136-137).

The physical attributes of wells that relate to their construction and primary function of providing water are the principal focus of this study. It is hoped that this project will contribute to an understanding of the different types of wells used in Delaware, and their temporal and geographical distribution. By compiling data related to wells already excavated in the state, we hope to elaborate on what we have already learned, and what substantive or methodological gaps may exist in the current dataset. From these, best practices for excavation may be derived along with priorities for future research.

3.0 METHODS

3.1 Archival Methods and Research Design

A literature review was conducted to investigate historical wells as an archaeological feature type in Delaware and to gather available data pertaining to previously excavated historical wells. The literature review was conducted at the DESHPO archives in Dover and through online sources such as DelDOT’s public report database and the Library of Congress. Full technical reports for sites with investigated wells were obtained in electronic format from DESHPO and DelDOT. International, national, and regional journals were reviewed for historical context and articles pertinent to historical wells in the Middle Atlantic region including *Historical Archaeology*, the *Journal of Middle Atlantic Archaeology*, and the *Bulletin of the Archaeological Society of Delaware*. Field records and management summaries for well features with unpublished site data were reviewed at the DESHPO curation facility (e.g., Thompson’s Loss and Gain and Webb’s Landing sites) or through personal communication with the site investigators (e.g. Avery’s Rest Site and recent Route 301 data recovery investigations). Individuals with extensive experience in historical archaeology in Delaware were contacted to solicit recommendations and insights regarding particular studies, site reports or repositories. Those contacted included DESHPO staff, active members for the Archaeological Society of Delaware, University of Delaware faculty, and current DelDOT consultants.

Site data were used to populate a table listing selected attributes for each well feature identified during the literature review including provenience information, environmental setting, construction methods and materials, pertinent measurements, and archaeological excavation methods employed (Table 3.1). The data from 58 excavated wells and 12 unexcavated wells were compiled in MS Access to facilitate organization and analysis and then exported to MS Excel for presentation and distribution. The field entries within the data table were largely obtained from narrative descriptions, feature summary tables, photographs, or plan and profile figures presented within the technical reports. In several cases, the technical reports for particular sites contained insufficient information to populate all data fields.

Table 3.1. Historical Wells Data Table Fields		
Field Name	Description	Source
Well ID	Unique identifier for each well	Combination of site and feature number (i.e., 7NC-J-175/F171)
Site Number	State trinomial	DESHPO
CRS Number	Survey Number Assigned	DESHPO
Site Name	Common or local name or other designation	Technical report/field records
Site Type	Domestic, industrial, agricultural, etc.	Technical report/field records
Site Description	Brief site description/summary	Technical report/field records
County	County in which site is located	Technical report/field records
Hundred	Hundred in which site is located	Technical report/field records
Watershed	Watershed in which site is located	Technical report/field records
NRCS Soil Type	NRCS soil type for site/feature area	NRCS web soil survey

Table 3.1. Historical Wells Data Table Fields		
Field Name	Description	Source
Feature Number	Number or other designation used during archaeological investigation	Technical report/field records
Well Lining	Lining type (i.e., brick, stone, barrel)	Technical report/field records
Well Shape	Shape of well excavation (i.e., round, square)	Technical report/field records
Well Setting	Feature setting within site (i.e., rear yard, work yard)	Technical report/field records
Construction Method	Notes on methods and materials used	Technical report/field records
Feature Notes	Excerpts/paraphrased notes pertaining to construction and conditions	Technical report/field records
Period of Use	Date range well was in use	Technical report/field records
Dates_Occupation	Date range for site occupations	Technical report/field records
Dates_Fill	Date range for well fill	Technical report/field records
Dates_Builders	Date range for builders trench	Technical report/field records
Chronology Notes	Basis for use, occupation, fill, builder's trench dates	Technical report/field records
Nearest Water	Name or description of nearest permanent water source	USGS 7.5 minute topographic map
Distance to Water	Distance in feet to nearest permanent water source	USGS 7.5 minute topographic map
Distance to House	Distance in feet from well to main domestic structure ¹	Technical report/field records
Distance to Kitchen	Distance in feet from well to kitchen	Technical report/field records
Distance to Outbuildings	Distance in feet from well to outbuilding, and outbuilding type	Technical report/field records
Excavation Methods	Excavation methods used (i.e., hand or mechanical)	Technical report/field records
Excavation Methods Notes	Brief narrative of methods or additional information on methods	Technical report/field records
Special Analyses	Special analyses conducted on well materials (i.e., brick or soil chemistry)	Technical report/field records
Depth	Total depth of well in feet	Technical report/field records
Excavated Depth	Depth of well as excavated, if not fully excavated (in feet)	Technical report/field records
Diameter Exterior	Dimensions of well opening, exterior (n-x-n)	Technical report/field records
Diameter Interior	Dimensions of well opening, interior (n-x-n)	Technical report/field records
Contents	Brief summary of well contents	Technical report/field records
References	Full citation of technical report	Technical report/field records

Using the collected data, a geographic information system (GIS) was developed with ESRI ArcGIS 10.1 software to facilitate analysis of the data and to prepare a map showing all sites in Delaware with excavated wells. Base map data such as state, county, hundred, and watershed boundaries were obtained from the Delaware Geospatial Data Exchange (DTI 2012). Site location data were obtained in GIS shapefile format from DESHPO. Soil data were downloaded from the United States Department of Agriculture (USDA), Natural Resources Conservation Service (NRCS), Web Soil Survey (USDA-NRCS 2013). The identification of the nearest permanent water source to each site

¹ distances from wells to related structures were calculated between the center points of the features

represented in the data table and distance to water calculations were performed in the GIS using a USGS 7.5 minute topographic map layer (ESRI 2013). Modern water table data were obtained from the Delaware Geological Survey (2005 a, b, and c) and from the USDA-NRCS Web Soil Survey. To preserve site location confidentiality, only center-point data for each site displayed on a statewide-scale map were used to present results of analyses conducted in support of the alternative mitigation.

4.0 TABULAR RESULTS

Versar reviewed more than 100 archaeology reports prepared for DelDOT over the last 30 years. That review found 70 wells that have been identified across the state as a result of archaeological research conducted in advance of highway improvements. Of these, 58 were subjected to intensive excavation. Wells have been found on historical home sites, farmsteads, dairy farms, stores, and blacksmith shops dating from the late 1600s through mid-1900s. Table 4.1 shows the data and observations about each of the wells included in this study. Complete results are included in Appendix A and B.

5.0 ANALYSIS AND CONCLUSIONS

5.1 Well Construction

Material

Wells in the sample were lined with brick, stone, wood planks, wood barrels, and in one case, a hollow log (Table 5.1). There were also a few wells that combined materials (2 lined with brick, but with a barrel at the bottom, 1 brick well with 4 courses of stone at the top, and 5 wood-framed wells with barrels at the bottom). Well types based on materials in the sample include the following:

- **Brick-lined:** wells lined entirely by brick. These were generally single wythe (one brick wide) and un-mortared.
- **Brick/barrel-lined:** wells lined mostly with brick, but that had a barrel at the bottom of the well.
- **Brick/stone-lined:** wells that employed a combination of brick and stone for lining. There was one such well in the sample; it was primarily lined with brick, but the upper courses were of stone.
- **Barrel-lined:** wells lined entirely by stacked barrels. The barrels have had their tops and bottoms removed, and are stacked one on top of the other within the well to provide a lining.
- **Stone-lined:** wells with linings made entirely of stone.
- **Wood box-lined:** wells with rectangular wood frame linings.
- **Wood box/barrel-lined:** wells primarily lined with a rectangular wooden frame, but with a barrel at the bottom.
- **Wood plank-lined (circular):** circular wells lined with vertical wooden planks.
- **Hollow log:** a well consisting of a hollowed-out log.
- **Unidentified:** owing to the state of preservation, a number of well features were not identifiable by lining type or material. These were most likely lined with perishable materials such as wood frames or barrels. But it is also possible that they could have been lined with brick or stone that was salvaged when the well was abandoned.

Brick-lined wells were overall the most common, followed by wood-lined, and stone-lined. Brick-lined wells were all single wythe (1 course thick), and mostly made with ordinary bricks. The well at Boyd's Store and House used bricks with glazing. The description of the wells at the Darrach Store site mentioned "specially shaped 'well bricks' (which are wider at one end than the other)" (DeCunzo et al. 1992:102). Curved, or radial bricks, are sometimes used when a smooth curve is desired in a masonry wall (Perlman 1993). The bricks at the Narbonne House well, in Salem, Massachusetts, were curved in this way (Moran et al. 1982:41). However, the well at the Darrach store is the only well in our sample to use these. Most of these wells were circular in shape, with the exception of wells lined with wood box structures.

Most of the wood-lined wells were rectangular, though there were also two circular wood plank lined wells, and one that consisted of stacked, 2-foot diameter hollowed out larch logs (Feature 219 at 7S-K-118, the Laban Rogers Site). Feature 11, the earlier of two wood-frame wells at 7S-G-57, the Avery’s Rest site, had square corner posts driven into the subsoil with wood plank framing. This well at the site appears to have been repaired by inserting a deeper, narrower frame inside the first (Figure 5.1). The barrel wells usually consisted of three barrels with the top and bottom removed stacked on top of each other (Griffith personal communication 2014; Figure 5.2).

Table 5.1: Well Types and Frequencies

<i>Well Lining</i>	<i>Excavated</i>	<i>Unexcavated</i>	<i>Total</i>	<i>Freq.</i>
Brick-lined	15	5	20	29%
Brick/barrel-lined	2	0	2	3%
brick/stone-lined	1		1	1%
Barrel-lined	6	0	6	9%
Stone-lined	6	1	7	10%
Wood box-lined	10	0	10	14%
Wood box/barrel-lined	5	0	5	7%
Wood plank-lined (circular)	2	0	2	3%
Hollow log	1	0	1	1%
Unidentified	10	6	16	23%
<i>Total</i>	<i>58</i>	<i>12</i>	<i>70</i>

Figure 5.2: Feature 268, Barrel Well from 7NC-J-204, the Jones Site.

In a few instances, excavated wells appeared to have the remains of associated structures as indicated by postholes or masonry (Table 5.2). These have been interpreted as evidence of well coverings or a small shed. Such coverings would have helped to keep foreign matter out of the well, and could have housed buckets, pulleys, or pumps to help bring water out of the well. Four wells in the sample included the remains of a pump, Feature 5 at the Bloomsbury Site (7K-B-23), Feature 17 at Whitten Road (7NC-D-100), Feature 2 at the Thomas Williams Site (7NC-D-130), and Feature 14 at the Armstrong-Rogers Site (7NC-F-135). The Armstrong Rogers well also may have included the remains of a curb, a wide wooden ring used at the bottom of the well excavation as a base for the lining, and in this case possibly a support for the pump stock (Figure 5.3). There were two wells, both made of wood, which appeared to use linings to help control or purify water: lime in Feature 697 at the Houston-LeCompt Site (7NC-F-139) and clay in Feature 2 at the Bay Vista Site (7S-G-26).

An approximate quarter-century time frame was assigned to each well in the sample (Figure 5.4). When provided, the report author’s estimates were used. However, builder’s trenches were not always evident, and in such cases, especially if only one well was found at the site, the well construction date was assumed to be coincident with the establishment of the site. Where there appears to have been a succession of wells, the construction date was estimated based on the apparent date of an earlier well’s abandonment. This sometimes came from datable artifacts in the well fill. In a few instances, dendrochronology dates were available (e.g., the Cardon/Holton and Armstrong Rogers Sites). Quarter-century date estimates for the wells are shown in Table 4.1.

The earliest wells in the sample were all lined with wood until the second quarter of the 18th century. Most of these early wells were rectangular wood plank wells, though there is a wood plank well with a barrel at the bottom dating from probably the first quarter of the 18th century. Barrel-only wells appear in the sample by the third quarter of the 18th century, and seem to persist until the third quarter of the 19th century. Brick well linings appear in the second quarter of the 18th century, and continue through the latest wells included in the sample. The first stone-lined wells date from the last quarter of the 18th century.

This makes some intuitive sense, and mirrors patterns in construction materials used for other structures. Brick makers and bricks may not have been widely available in the earliest years of European settlement, while wood would have been abundant. Barrels might also have been common, and an easy expedient for lining a shallow well, compared to the level of effort that would have been needed to line a well with brick or stone.

Depth

Perhaps one of the most salient characteristics of the wells in our sample is that many of them are very shallow. None of those for which bottom depth was available is deeper than 30 feet, and all but 4 of those are 15 feet deep or less (Figure 5.5). Three other wells were excavated to below 20 feet, but the bottom was not documented for these. This has obvious implications for the technology used to dig and line these wells, as well as for the potential reliability and quality of the water obtained. One advantage of having a shallow water table is that they can be dug quickly and easily without specialized equipment, and you can get away with fairly expedient technologies and linings, like barrels. On the other hand, such materials might be more prone to fail than masonry linings, requiring that occupants dig new wells periodically. In fact 12 of the sites in the sample include multiple wells that may have been used in succession, including the Moore Taylor Farm (7K-C-380), which had five wells.

One significant problem with this data set is that depth was only recorded for 24 of the 58 wells excavated. The depth archaeologically excavated for the remainder of the sample (34 wells) ranged from 25 feet to less than 3 feet. Three were excavated to below 20 feet, the remaining archaeological tests were all terminated less than 14 feet from the surface, sometimes at or about the beginning of the water table. This is understandable given the challenges and hazards associated with excavation below the water table, but it poses an obvious dilemma for interpreting how well technology was used in Delaware. Answering the question about whether people in Delaware sometimes dug their wells deeper to avoid wells running dry requires that the bottom depth be determined and clearly documented. Material deposited at the bottom of wells can also help date the period of their use and abandonment. Material recovered near the tops of wells may be related to much later activity, perhaps when the site as a whole was abandoned.

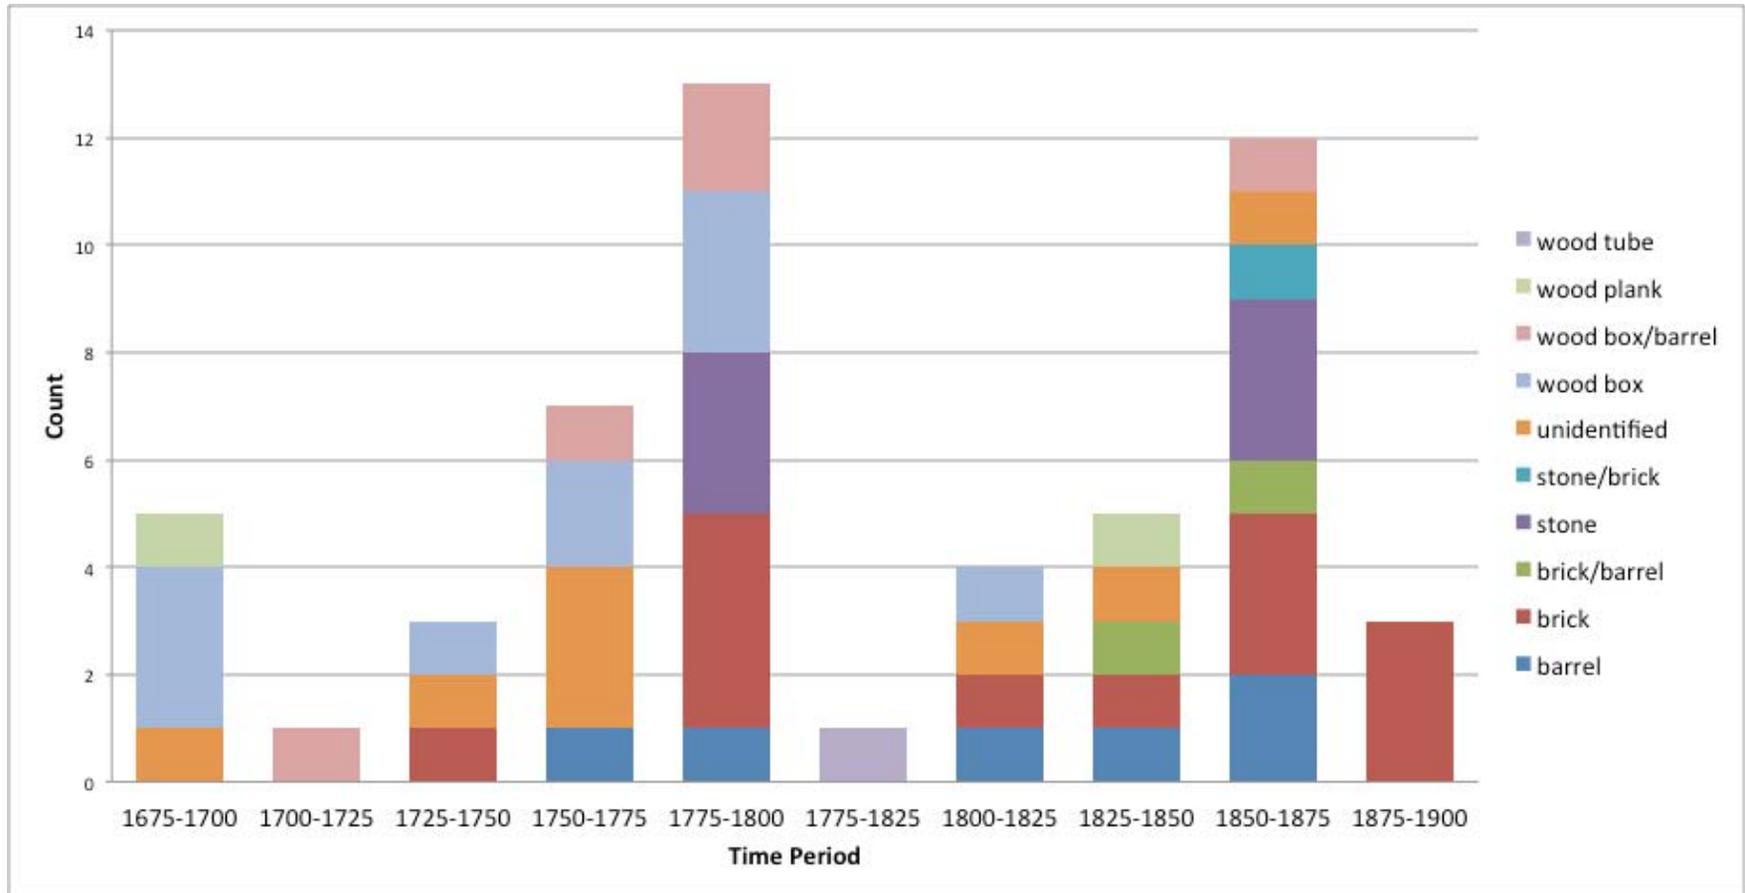

Figure 5.4: Well Types Chronologically

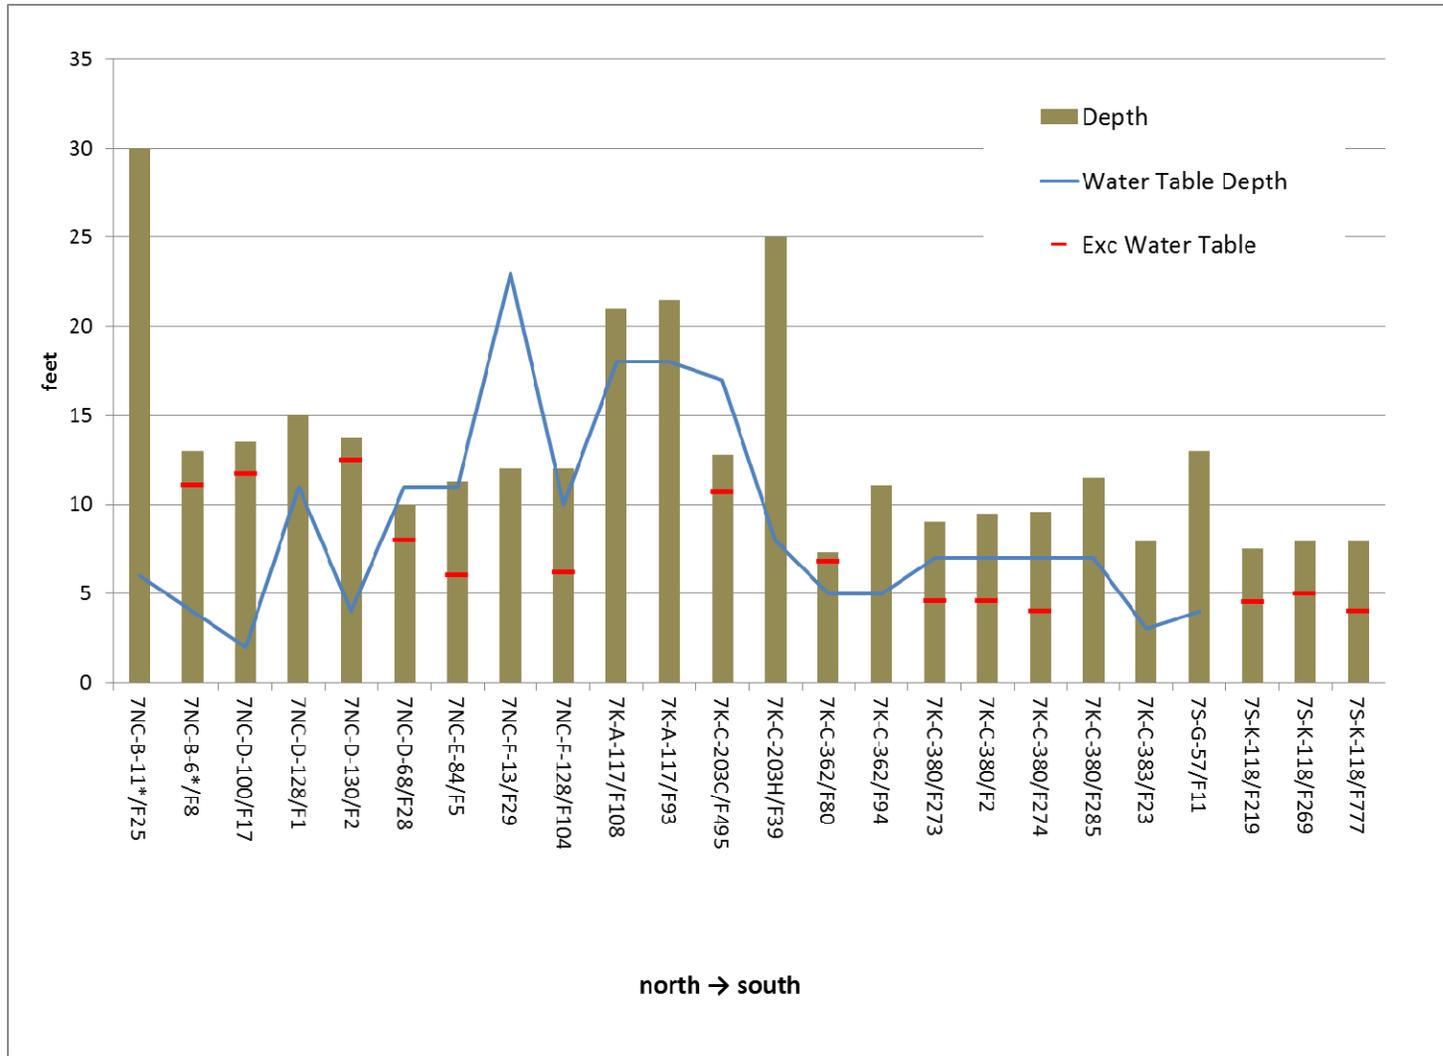

Figure 5.5: Depth of Wells: Red dashes indicate water table depth as recorded by archaeological testing. Blue line indicates water table from NRCS or DGS. *NRCS 1970, all others DGS 2005.

Shape and Dimensions

Circular wells in the sample ranged in size from 2 to 6 feet in diameter with an average of 3.1 feet. Square or rectangular wells similarly ranged in size from 2 x 2 feet to the largest (the Armstrong Rogers well) at 8.3 x 7.6 feet. Comparing well area by well type and approximate date shows that rectangular wood frame wells were the largest wells in the sample (Table 5.3, Figure 5.6). Barrels were the smallest, understandably perhaps since their diameter was essentially fixed by the size of available barrels. The next smallest were stone wells, then brick wells. Perhaps their small size compared to wood frame wells is a reflection of the greater relative cost of the materials. The overall temporal trend suggesting a drop in well size is probably mostly a product of the temporal trend towards brick wells.

Table 5.3: Average of Area of Well Openings by Type Through Time					
Row Labels	barrel	brick	stone	wood	Total

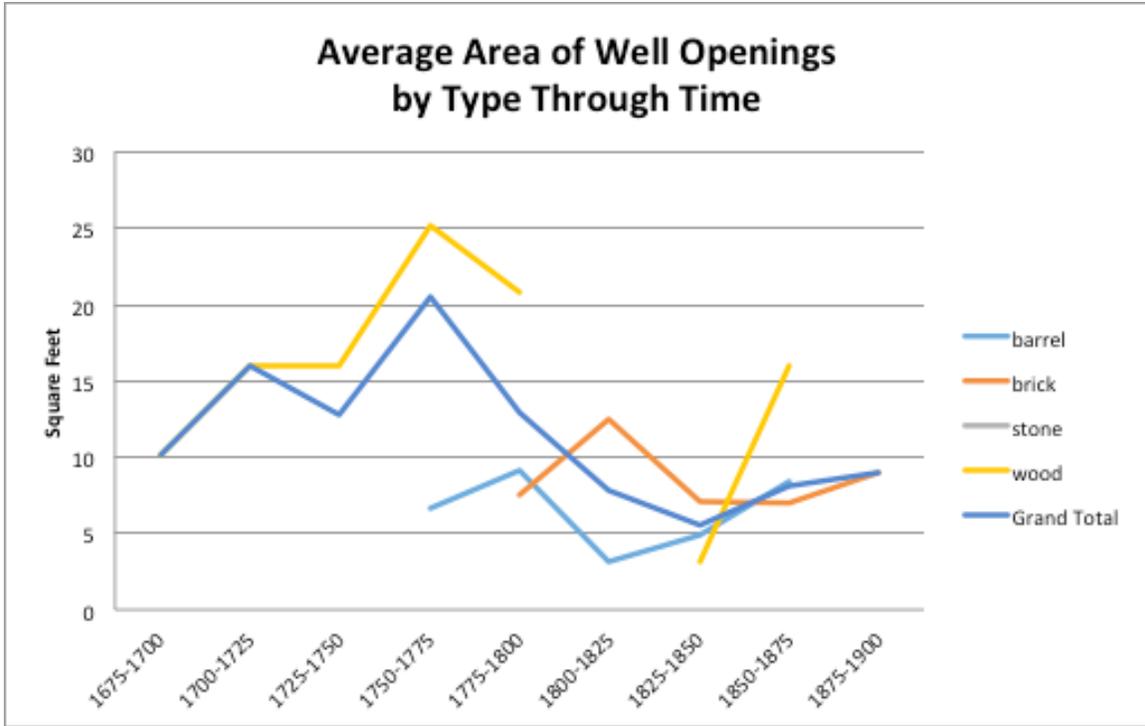

Figure 5.6: Average Area of Well Openings by Type, Chronologically.

5.2 Well Setting

Geographical Context

The geographical distribution of wells is shown in Table 5.4 and in Figures 5.7-5.11. The clearest geographical pattern that emerged from analysis was that all of the stone-lined wells excavated to date have been found in northern New Castle County. This is the only region of the state located in the Piedmont rather than the Atlantic Coastal Plain, and where stone as a material is relatively more abundant than elsewhere in the state. Stone would likely have been expensive to transport, so the pattern is not unexpected. Beyond that, it is difficult to discern other patterns with confidence since most of the wells found were in the northern half of the state. Thirty were found in New Castle, 21 in Kent, and only 7 in Sussex County. The extent to which this reflects the number of historic sites subject to excavation versus the actual spatial distribution of wells is unclear since statistics on the number of historic sites excavated by county in the state have not yet been compiled. The number of sites (historic and prehistoric) recorded is relatively similar across the three counties, so the geographical distribution of wells may not be random, and may reflect the relatively higher historical population density of the northern half of the state versus Sussex County, but the degree to which this reflects instead the distribution of archaeological projects is still unknown.

County	Sites with Excavated Wells	Total Sites	% sites with excavated wells	% of all sites in state recorded in county
Kent	21	1369	1.53%	34.0%
New Castle	30	1407	2.13%	34.9%
Sussex	7	1251	0.56%	31.1%
		4027		

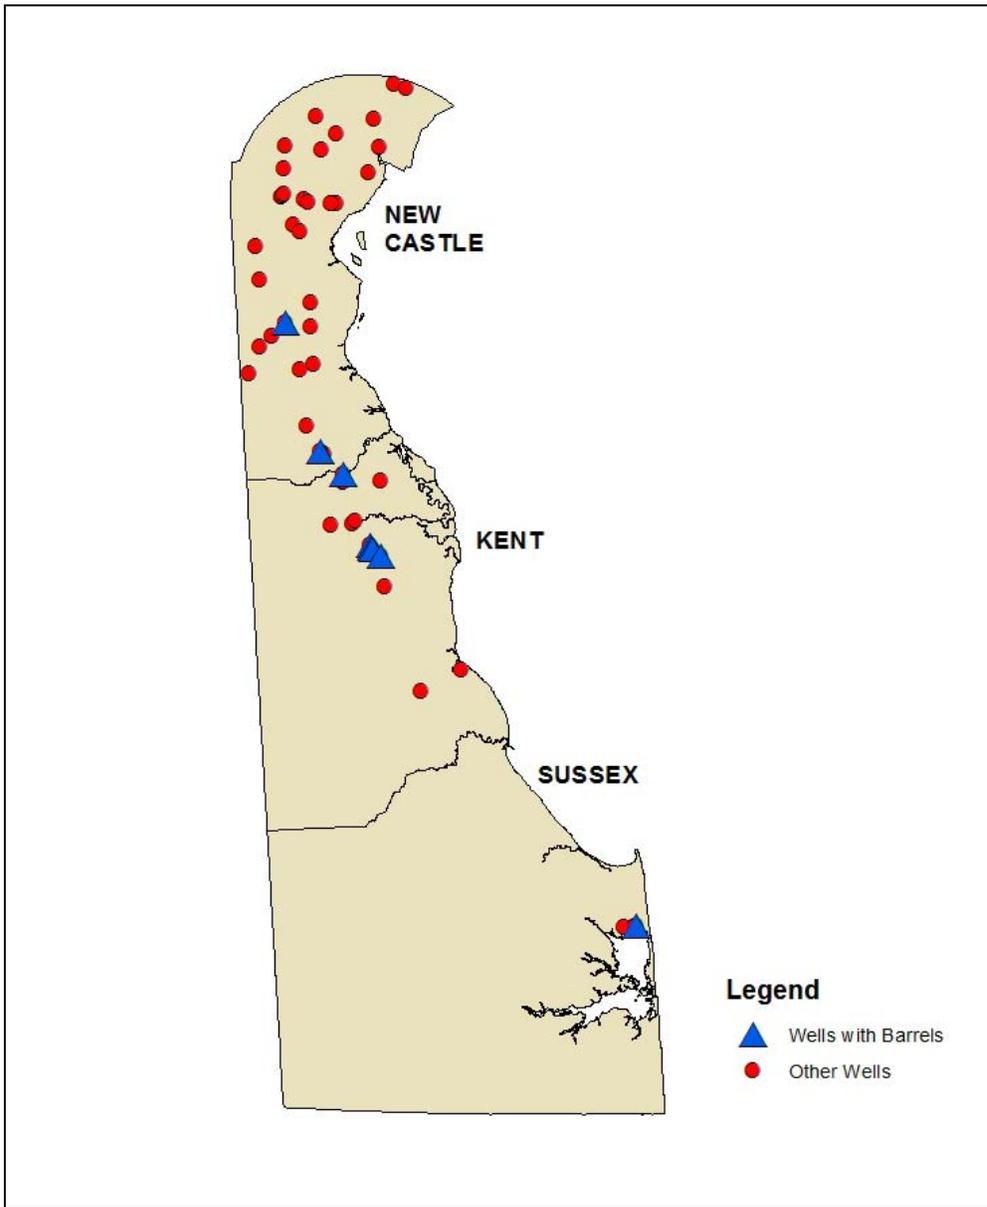

Figure 5.7: Barrel Wells

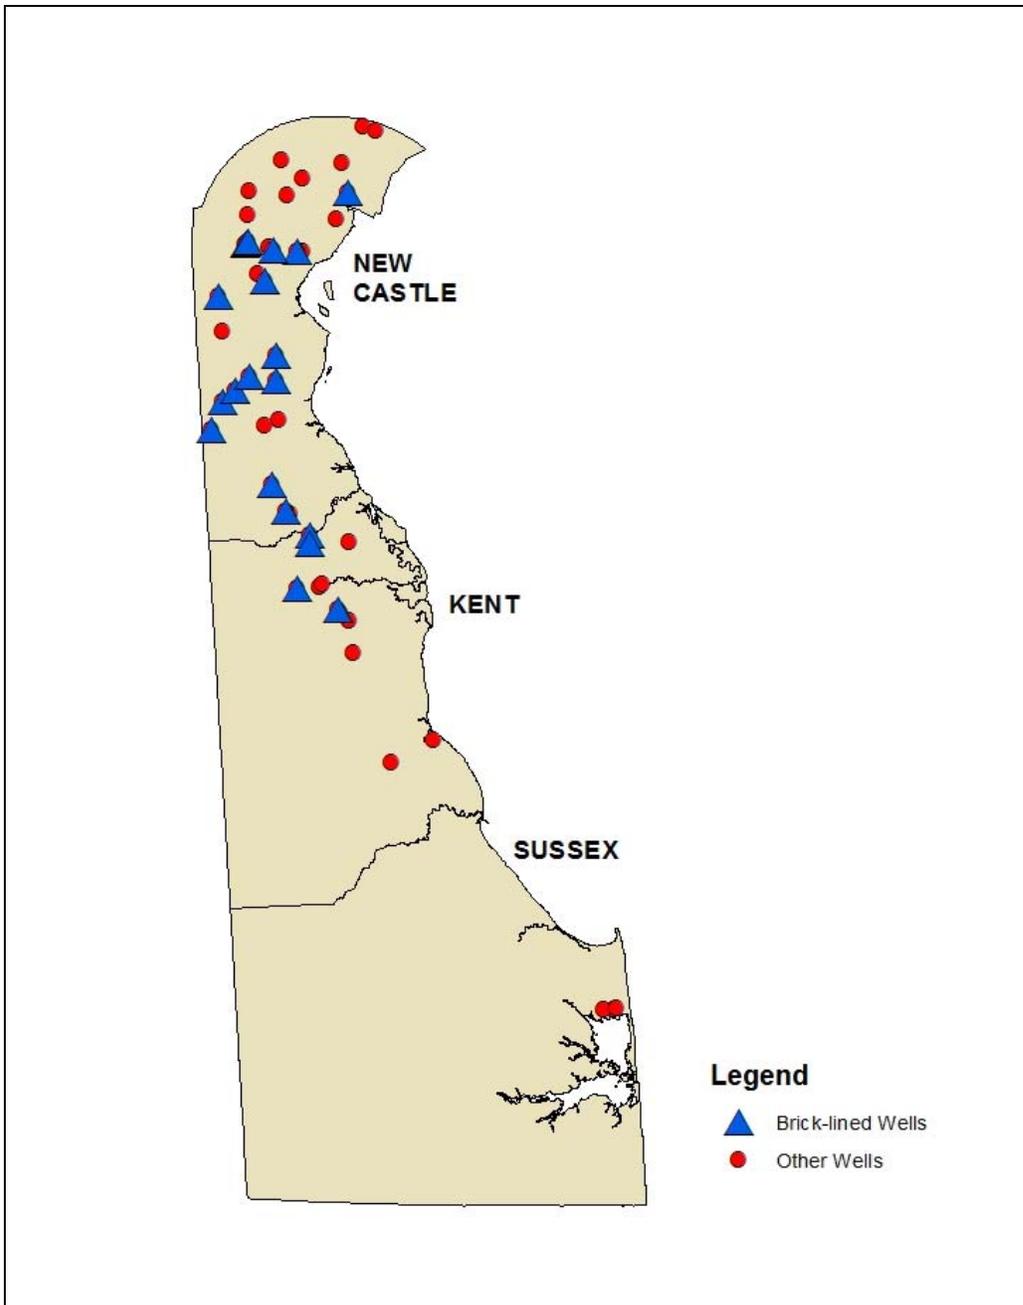

Figure 5.8: Distribution of brick-lined wells.

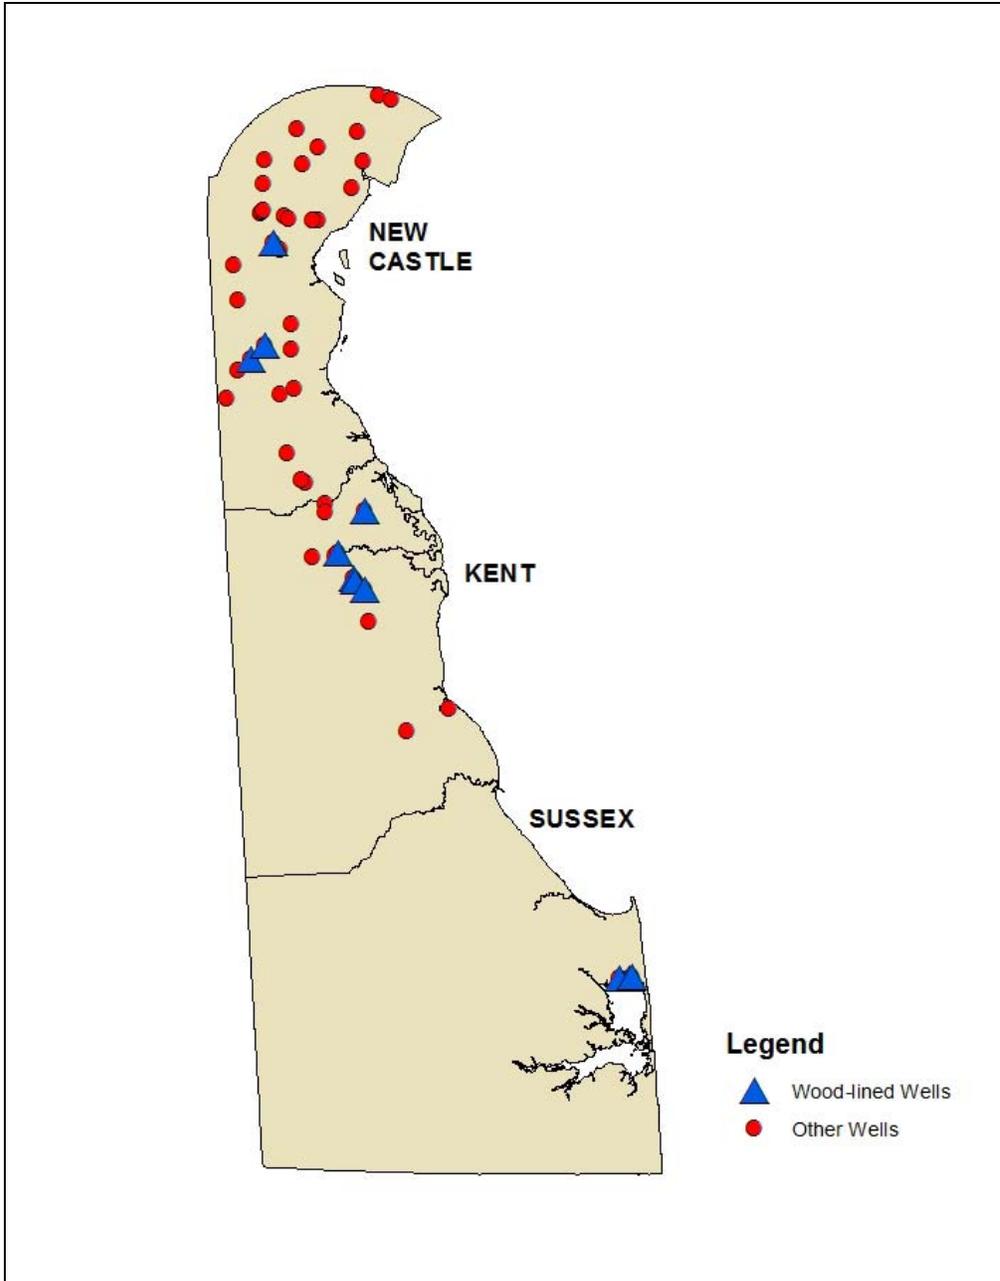

Figure 5.9: Distribution of wood-lined wells.

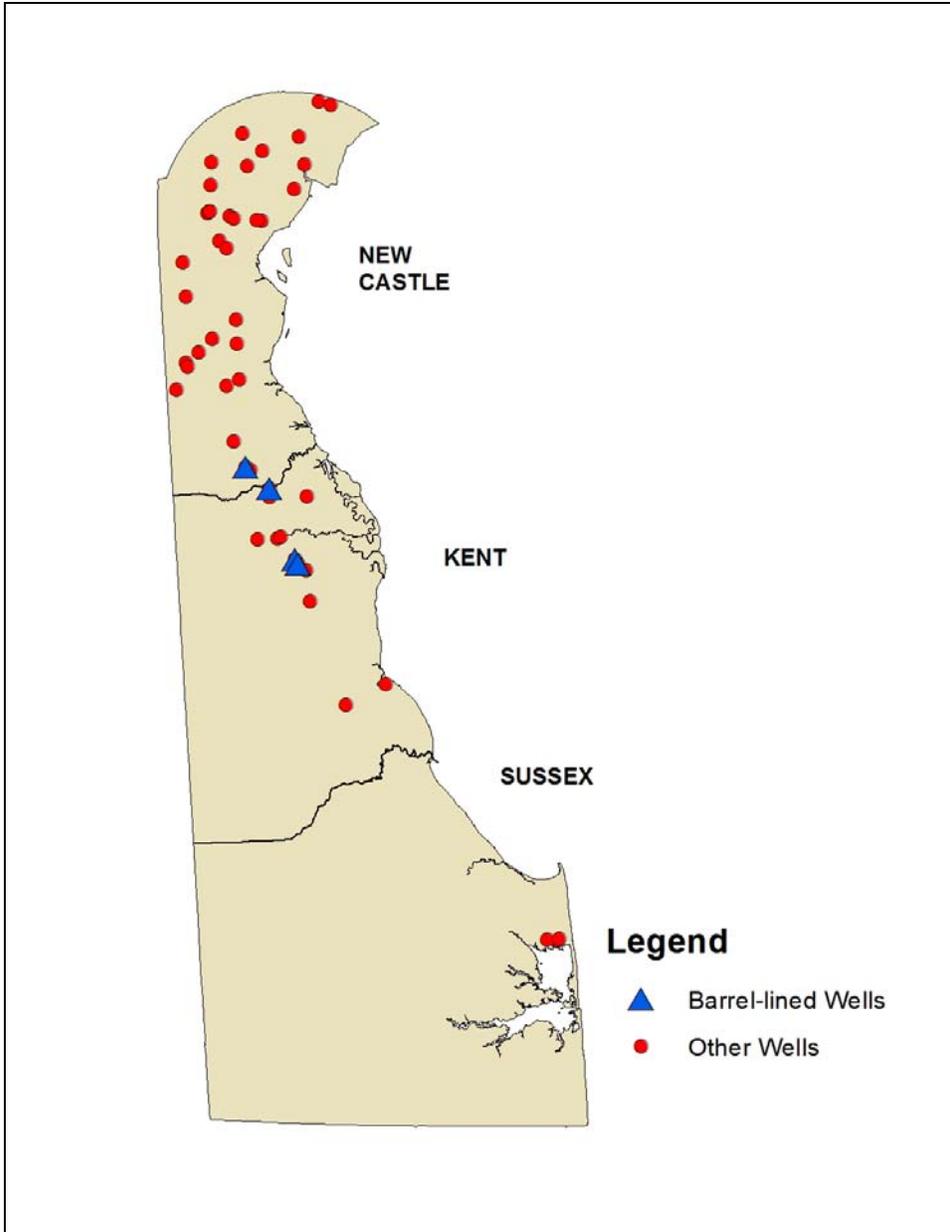

Figure 5.10: Distribution of barrel-lined wells.

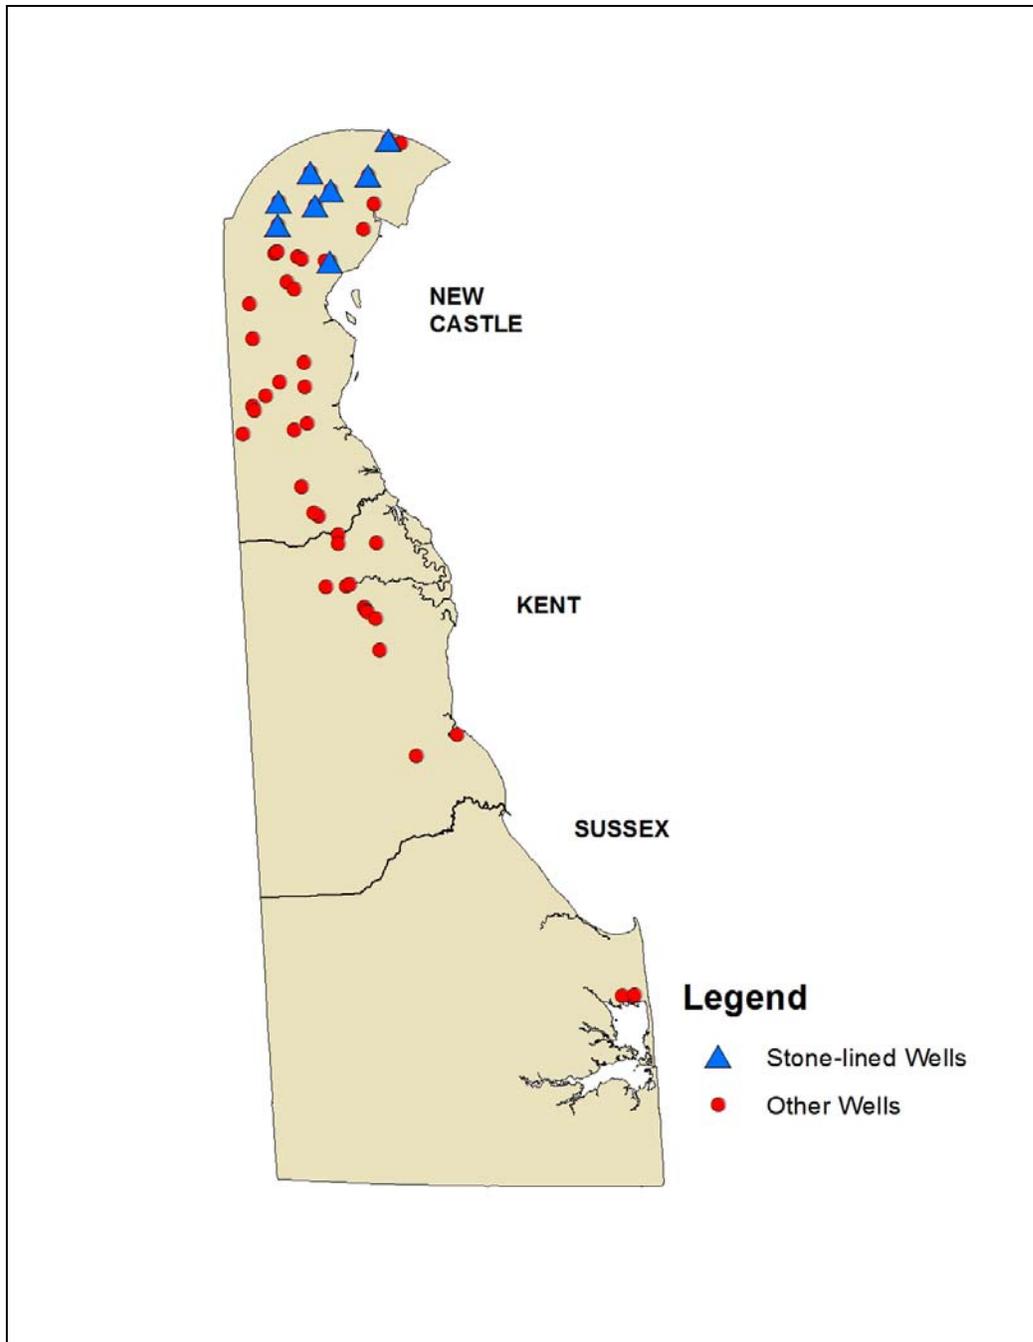

Figure 5.11: Distribution of stone-lined wells.

Site Context: Nearest structure

Most of the excavated wells were found relatively close to the principal site structure, usually a dwelling. Table 5.5 shows the average distance between excavated wells and the site dwelling by material for which this measurement was available (n=53) along with the minimum and maximum distance from the dwelling for each lining material along with the standard deviation. All of the averages ranged between 30 and 56 feet. However, there was substantial variation in the distances recorded. The greatest variability was found among wood frame lined wells, which were found as far away as nearly 200 feet from the dwelling. The average distance and variability are both reduced when the nearest structure of any kind is considered (Table 5.6). With the exception of wood box lined wells, excavated wells averaged about 20 feet from the nearest structure, with a range from 0 to 164 feet (0 feet indicated location inside a structure).

	Average	StdDev	Minimum	Maximum
Barrel	36.8	13.2	28.0	60.0
Brick	34.7	31.0	0.0	112.0
Stone	32.3	34.5	0.0	100.0
Unidentified	40.9	17.9	7.0	75.0
Wood	55.6	53.4	0.0	197.0
Total	42.8	38.2	0.0	197.0

	Average	StdDev	Minimum	Maximum
Barrel	23.0	9.9	10.0	33.0
Brick	21.1	16.9	0.0	50.0
Stone	19.0	9.6	0.0	25.0
Unidentified	19.6	18.2	0.0	50.0
Wood	35.7	42.3	0.0	164.0
Total	25.7	28.0	0.0	164.0

A lot of the variability in the wood-lined wells comes from two samples (Features 17 from Whitten Road and 578 from the Houston/LeCompt site). Repeating the calculations without those two outliers still shows the wood-lined wells to be further away on average than other well types, and more variable, but closer to the rest of the sample (Table 5.7).

	Average	StdDev	Min	Max
Barrel	23.0	9.9	10.0	33.0
Brick	21.1	16.9	0.0	50.0
Stone	19.0	9.6	0.0	25.0

	Average	StdDev	Min	Max
Unid.	19.6	18.2	0.0	50.0
Wood	22.3	16.0	0.0	50.0
Total	21.1	15.1	0.0	50.0

Table 5.8 compares the number of outbuilding wells by material to the total number of wells recorded. The percentage of outbuilding wells made with barrels or brick do not seem to differ substantially from their overall representation in the sample. However, the percentage of outbuilding wells that are made of stone and wood framing does differ. This may suggest that barrel and brick wells were no more or less likely to be associated with an outbuilding than with the principal structure on site, but that stone wells were more likely to be associated with a dwelling or other principal structure and wood-lined wells were more likely to be associated with an outbuilding. It makes sense given the relative effort to build a stone-lined versus a wood-frame well that stone-lined wells would be reserved for the most important structures on a site.

	Count	Total	% of material	% of outbuilding wells	% of all locations
Barrel	2	6	33%	8%	10%
Brick	6	17	35%	25%	29%
Stone	1	7	14%	4%	12%
Unid	5	10	50%	21%	17%
Wood	10	18	56%	42%	31%
Total	24	58			

Environmental Context: Distance to water

We considered the environmental context of the wells identified in the study, examining their distance to nearest water as well as the type and drainage characteristics of the soils in which they were dug. However, given the typical proximity of wells to site structures, especially the principal occupation structure, it is possible that these environmental variables have more to do with overall site selection than with parameters for selecting a well site. Given Delaware’s even topography and relatively shallow water table, finding a suitable well location may have been fairly easy, making other factors, like access to transportation and other overall site location parameters more important.

Charting wells (both excavated and unexcavated) according to distance to the nearest water shows considerable variability. Figure 5.12 shows the distance from surface water for 49 wells in the sample for which distance data were available. Wells were found as close as 50 feet from the nearest surface water, and as far away as over 4,000 feet. More than half of this sample (n = 26) were less than 1,000 feet from water (Figure 5.13). Overall, the distances seem fairly evenly distributed across the range. This may have

more to do with site selection characteristics than well selection, since most wells, at least those excavated, are very near site structures. One might expect earlier sites to be closer to water than later sites which might be distributed along Delaware’s growing network of roads, and did not need to be located on water necessarily. However, the data do not seem to support this as well features do not exhibit any clear trend chronologically with regard to distance to water (Figure 5.14). It appears that distance to water was not clearly an important factor in well site location.

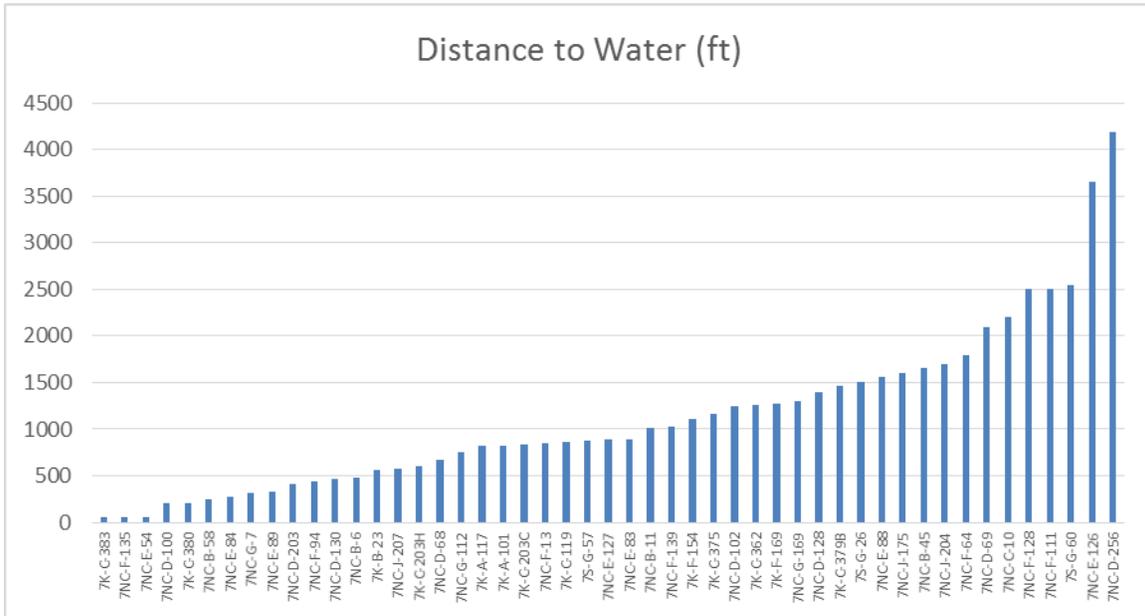

Figure 5.12: Wells by distance to water.

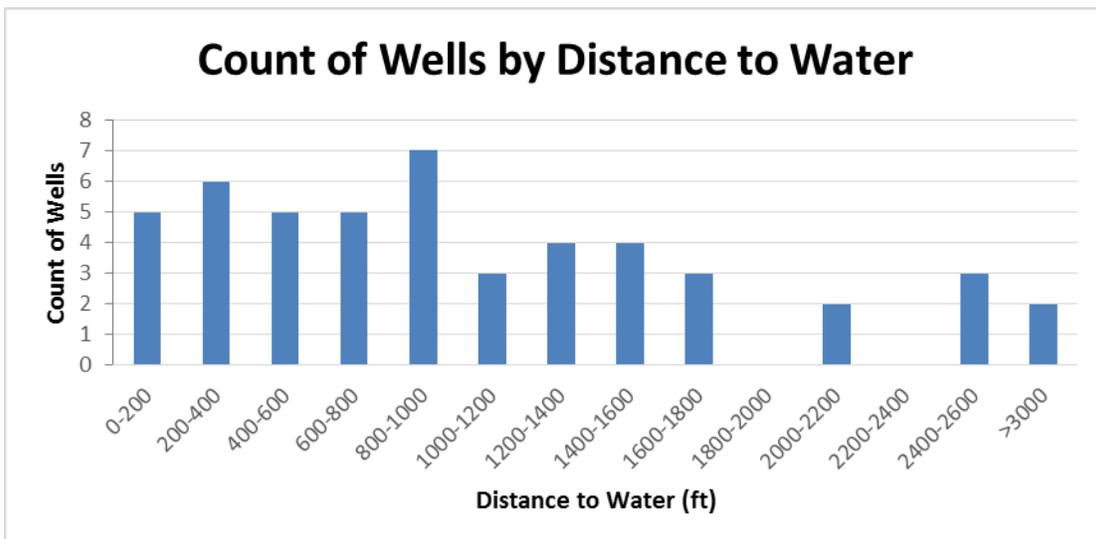

Figure 5.13: Count of wells by distance to water.

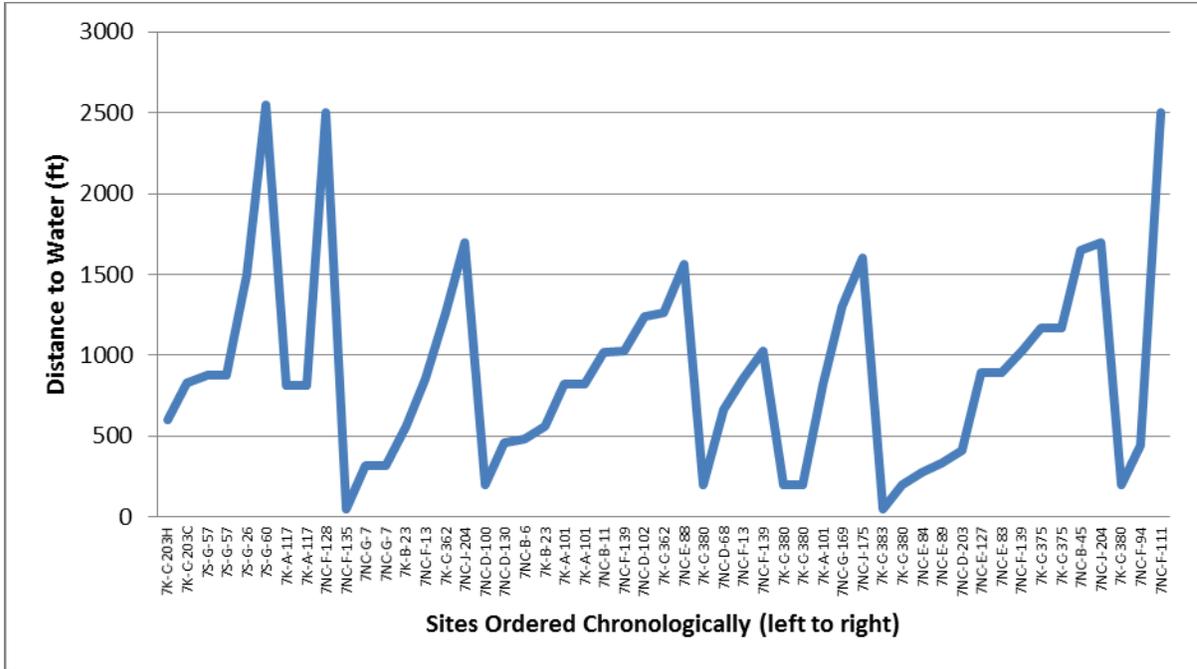

Figure 5.14: Well distance to water ordered chronologically.

Environmental Context: Soils

Soil characteristics can be expected to have affected how the well filled, how easy it was to construct, and potentially how often it may have needed to be repaired or replaced. The following tables (5.9, 5.10) show the mapped soil unit and drainage characteristics for the wells in the sample for which soils data were available (n = 49).

	Channery Loam	Loam	Loamy Sand	Mucky Loam	Sandy Loam	Silt Loam	Total
Barrel		3			1	2	6
Brick	1	2			4	5	12
Brick/Barrel		1				1	2
Stone		1		2	1	1	5
Unidentified		2	1		3	3	9
Wood Box	1	2	2			4	9
Wood Box/Barrel		2			2		4
Wood Plank		1	1				2
Total	2	14	4	2	11	16	49

	Well Drained	Moderately Well Drained	Poorly Drained	Very Poorly Drained	Total
Barrel	1	2	2		5
Brick	9	2			11

	Well Drained	Moderately Well Drained	Poorly Drained	Very Poorly Drained	Total
Brick/Barrel	2				2
Stone	2		1	2	5
Unidentified	6	1	2		9
Wood Box	7		2		9
Wood Box/Barrel	4				4
Wood Plank	1	1			2
Total	32	6	7	2	47

Note, information regarding drainage characteristics was not available for all recorded soil types.

Table 5.10 shows the drainage characteristics for soils identified for wells included in the sample. “Poorly drained” in the table includes soils that are poorly to very poorly drained, while the column “well drained” includes moderately well drained. The tables show that wells were more likely to be sited on well drained than poorly drained soils. Such locations might have been easier to dig, and more importantly, permeable soils are better at allowing water to move through the soil to refill the well. However, like distance to water, the siting of a well near the structures it was intended to serve may have had more to do with the location of wells than choosing soils with particular characteristics. Ideally a well should have been located on well-drained soil away from and at a higher elevation than potential sources of contamination. A potential avenue for future research would be to examine the topography, soil types and chemistry of a well and the site around it to see what environmental variables were important.

Social Context: Well Types and Ownership Status

Excavated wells in our sample were found in a variety of site-type contexts, including churches, community settings, and stores. Most, however, were found on farmstead sites. Among these, there are some differences between owner-occupied and tenant-occupied sites that may be worth exploring further (Table 5.11). A Chi-squared distribution analysis shows that this distribution is significantly different (p=.04). All of the barrel-lined wells in this sub-sample were found on tenant farm sites. Most of the stone-lined wells were from owner-occupied sites. If closer examination, and more data, sustain this pattern, it might suggest a higher frequency of expedient well linings like barrels at tenant occupied sites, and a greater frequency of higher cost linings, like stone, at owner occupied sites. But based on this interpretation, one would expect there to be more brick-lined wells at owner-occupied sites, and more wood-lined wells at tenant sites, but the opposite is true. One possible explanation for this is that wood-lined wells averaged earlier dates than brick-lined wells (mid to last quarter 18th century vs first to second quarter 19th century), while owner-occupied sites in the sample had an earlier average date than tenant-occupied sites in the sample (3rd quarter 18th century vs 1st quarter 19th century). Thus the pattern with wood-lined and brick-lined wells may have more to do with chronology than ownership status. Then too, the sample size is fairly small; the addition of new samples could easily change the pattern.

5.3 Well Contents

There has long been much interest on the part of archaeologists in the contents of wells. When abandoned while the site was still occupied and slowly filled with refuse that can be attributed to the site occupants, they offer well preserved, clearly stratified, and sometimes dense deposits of material related to site occupation. Deposition in water-logged soils can also promote the preservation of organic materials otherwise rare on archaeological sites, such as leather, faunal and floral remains. Unhappily, the interest is not confined to professionals. Numerous itinerant groups of avocational bottle collectors scavenge the contents of abandoned wells for collectible bottles. But how often do wells produce assemblages of potential interest in site interpretation?

At least 54 of the excavated wells produced artifacts in the well fill. Available reports were not always clear about the artifact counts from excavated well features, but of those that had those data available, at least 18 produced more than 500 artifacts, and 5 had more than 1,000. In some cases, much of the material consisted of demolition debris recovered from the uppermost part of the shaft. Such assemblages (such as the wells at the Heisler house site and the Heisler tenant site) arguably have relatively low research value. Research value here is simply an estimate of the likelihood the assemblage may be useful in addressing questions of archaeological interest. However, 30 wells, more than half of those excavated, had significant quantities of non-architectural material. These 30 wells appear to be heterogeneous in material type and date. It does not appear that wells of any particular construction type or date are any more or less likely to contain significant domestic artifact deposits (Tables 5.12 and 5.13).

Table 5.12: Artifact Assemblage Research Value by Well Type				
Well Type	Low	Med	High	Grand Total
Unknown	5	1	4	10
barrel	2	1	3	6
brick	5	3	9	17
stone	1		5	6
wood	3	3	9	15
Total	16	8	30	54

Table 5.13: Assemblage Research Value by Period				
Decade of Construction	Low	Med	High	Total
1675-1700	1		4	5
1700-1725		1		1
1725-1750			2	2
1750-1775	1	2	3	6
1775-1800	2	1	7	10
1800-1825	1	2	1	4
1825-1850	4		1	5
1850-1875	3	1	7	11
1875-1900	2	1		3
Total	14	8	25	47

Different contents can generate different interpretations; e.g., at the W. Eager Farmstead (7K-C-383), the fill was generally unstratified and contained few historical artifacts, suggesting to the researchers that it had been intentionally filled in, probably with dirt from another part of the site or from off-site altogether.

The wells that do contain substantial, stratified deposits of artifacts deposited either by accident while the well was in use or after it was abandoned, could provide information about the behavior of people at the site. Table 5.14 lists the well assemblages from Delaware that appear to have the highest artifact-related research value, along with a brief

summary of the contents. This is based on descriptions in the associated reports that show large numbers of artifacts not dominated by demolition debris.

Table 5.14: Well Artifact Contents		
Site_Name	Contents	Quantity of Material
Laban Rogers House F219	Artifacts recovered from builders trench and shaft; Domestic, personal items, hardware and floral/faunal remains; extensive artifact list presented in report text. Included redware, Westerwald, creamware, pearlware.	Not noted
Laban Rogers House F269	Several elements of the box frame and barrel were recovered from identification. Artifacts recovered from builders trench and shaft; Domestic, hardware and floral/faunal remains; extensive artifact list presented in report text. Lack of personal items su	Not noted
Laban Rogers House F777	800+ ceramic fragments along with domestic, personal, and hardware items; extensive table provided in report; includes pearlware, stoneware, creamware, delft, and redware.	800+
John Powell Plantation F39	Well Shaft: architectural and domestic artifacts (n=2,124); floral remains; faunal remains (n=3,039); 90% from uppermost 3 ft.	5163
Benjamin Wynn Tenancy F94	Well shaft: n=2,293: fill not stratified; contained domestic and architectural artifacts and faunal remains. Builder's trench n=108 domestic and architectural artifacts.	2293
John Darrach Store F99	Contains store demolition rubble: foundation stones and mortared brick; suggests well was open into mid-1860s; artifacts recovered from well fill (n=697) include domestic, architectural; hardware, faunal items. F99 contained 20 ceramic crossmends with 14 features.	697
William Strickland Plantation F108	Primarily domestic items.	Not noted
William Strickland Plantation F93	Primarily domestic items.	Not noted

Table 5.14: Well Artifact Contents		
Site_Name	Contents	Quantity of Material
Benjamin Wynn Tenancy F80	Feature 80 was filled in three main episodes. Each episode corresponds to the vertical distribution of historical artifacts. The displaced subsoils of Soil B were deposited when the well was initially constructed. Soils C and then A were then deposited into the well shaft after the well was abandoned. Based on this overall sequence, the artifacts of the builder's trench, Soil B, would be older than the artifacts of the two well shaft deposits. Domestic items; faunal remains.	Not noted
Wilson-Lewis Farm F123	n=607 artifacts; Domestic 58%, Architectural 25% - predominantly wire nails; floral remains.	607
Moore-Taylor Farm F285	1,000+ artifacts near base; mostly domestic; upper portion of well filled with tree stumps and demolition debris.	1000
Moore-Taylor Farm F273	515 artifacts, mostly domestic items.	515
Webb's Landing	Artifact collection stored at DE SHPO. Contains tin-glazed, salt-glazed, and earthenware holloware sherds. Pipe stem and bowl fragments. Pipe bowl stamps indicate R. Tippet and Evans (Bristol Export). Domestic and wild faunal remains; oyster and conch; corn cob fragments.	Not noted
Weldin Plantation F25	Included 52% domestic artifacts, 27% indeterminate, 18% architectural, and 2% ecological.	788
Pierce/Talley House	The artifacts include fragments from a George Washington portrait flask manufactured at the Dyottville Glass Works in Philadelphia in the 1840s, a tumbler base, an embossed beer bottle fragment, an amber bitters bottle fragment, lamp chimney fragments, greybodied salt-glazed stoneware cuspidor sherds, slip trailed redware plate sherds and an ironstone granite-china saucer rim sherd with a molded wheat and black berry border manufactured in England, ca. 1850-1873.	Not noted
Grant Tenancy F8	11 feet of rubble over primarily domestic artifacts in sediment.	Not noted
Whitten Road F17	Demolition debris, domestic items.	Not noted

Table 5.14: Well Artifact Contents		
Site_Name	Contents	Quantity of Material
Bernard Glatz House F21	Including 19th century redware, many different forms of whiteware, including 1830s and 1840s styles, nails, screws, a black glass 2-hole button, leather scraps, brick fragments, and oyster shells.	1000
Thomas Williams F2	Domestic, activity, architectural, faunal, personal.	Not noted
Springer/Ward/Little Farm F918	Artifacts consisted of beverage and milk bottles, large sherds of ironstone and porcelain, a 1929 Lincoln Head wheat cent, a glazed ceramic door knob, cutlery, tools, and a brass plate. Overall, they suggest that the well was filled in the second quarter of the 20th century.	Not noted
Forrest Street Shaft Feature	n=694; Artifacts recovered were primarily domestic in function. The soil, ash and slag layers recorded in the matrix were interpreted as a contemporaneous fill sequence with cultural materials that indicating that the procedure took place at the turn-of-the-century.	694
Bethel Church F1	The well had no stratigraphy per se, as it was filled with bottles and trash and not with soil. Among the whole bottles found in the well were 51 square Manishevitz. 16 whole Thunderbird. 2 Richards Wild Irish Rose. 2 Miller beer, 3 juice. And 16 Gallo Wine. This account does not include the many broken bottles that were also present.	Not noted
Clayton Farm F1	Artifacts related to site occupation (n=3,796): domestic, architectural, fuel, bone shell; frequency increased with depth.	3796
Armstrong-Rogers F14	Top deconstruction level contained 105 artifacts: one metal hook or latch, 22 nails, two milk glass, one pipe stem and five brick samples. Second level contained 183 artifacts: one button with thread, two flat glass, five vessel glass, five wood samples, plaster samples, seven lithics, 62 iron pieces and 100 ceramics. One-hundred and seventy pounds of brick and 136 pounds of rock were discarded from this feature.	288
Robinson Plantation F7	n=1000+; not specified in report; extensive ceramic description.	1000+

Table 5.14: Well Artifact Contents		
Site_Name	Contents	Quantity of Material
Jones F156	621 total artifact count; Upper Fill: Creamware (undecorated); whiteware (undecorated); cut nail; cut/wrought nail; wrought nail; Lower Fill: Pearlware (blue shell-edged); barbed wire; cut nail; cut/wrought nail; wrought nail; Builder's Trench: none.	621
Jones F268	199 total artifact count; Barrel 1(top): Pearlware (hand painted); white salt glazed stoneware (scratch blue); cut nail; wrought nail; Barrel 2(middle): Pearlware, cut nails; Barrel 3 (bottom): Creamware (undecorated); cut nail; blown in mold glass, Pearlware, Chinese porcelain; Builder's trench: Creamware.	199
Bay Vista F2	Including fragments of red earthenware, combed slipware, tin-glazed earthenware, nail fragments, clay tobacco pipe fragments, and a flake. Although the fill deposited in Feature 8-2, the well, were clearly stratified, there were so few artifacts recovered from the feature that stratigraphic analysis of this feature was not considered significant.	607
Avery's Rest F11	"German stoneware, English stoneware, tin-glazed stoneware, red-bodied earthenware, bone, shell, brick, iron artifacts including scissors and hoe, Staffordshire ceramics, white clay tobacco pipes. Well casing made of white oak. Remaining portion preserved by water table at 8 ft below base of plow zone."	
Avery's Rest F7	Well shaft contained a quantity of demolition debris (i.e. bricks, plaster, window glass, and nails) as well as household refuse (e.g. bone, shell, tin-glazed earthenware, white clay tobacco pipes, copper alloy pins, lead scraps, lead shot, red-bodied earthenware, bottle glass, copper alloy artifacts, stonewares).	

5.4 Polk Site Well in Context

The one-meter diameter circular brick-lined well found at the Polk site appears to have been built between 1895 and 1899 (based on the feature contexts, the artifacts recovered from these features, and available historical documentation). William Taylor likely owned the farm and constructed the Polk Tenant Site structure between 1895 and 1900. The bricks are dry laid, and single wythe — one course thick — typical for brick-lined wells in Delaware. It was dug 2.3 ft from the house, and is approximately 2,500 feet from an unnamed tributary of Sandy Branch.

Because the site was not subject to traditional mitigation, there are limits to what we know. The site was abandoned and razed during the 1930s. Only the top 3 feet of the well was excavated, so we do not know the bottom depth. The well, (labeled Feature 7 in the field) yielded 122 artifacts. Feature 7 yielded 122 artifacts dating from the mid 19th century to the 20th century. Artifacts included brick, mortar/plaster fragments, cut and wire nails, stoneware sewer pipe, window glass, brick fragments, mortar/plaster fragments, vessel and bottle glass; wire and barbed wire; a horseshoe, whiteware sherds, an aluminum can pull tab, and sheet metal. Overall, the impression left by this assemblage is that it relates to site demolition rather than material discarded into the well while the site was occupied.

That the well contents may have comprised primarily demolition debris could have limited what the well might have contributed to an understanding of the Polk Site. However, along with all the other wells excavated in Delaware, it helps to flesh out the overall context of wells in the state. In construction material, date, and distance to the house, it fit well within the patterns found among wells in Delaware described in this report, although it is at the farther end of the observed range for distance to nearest water. It is one of 12 all-brick wells in the sample, and like 7 of these, it was found on a tenant-occupied site. It is at the late end of the chronological range of wells in our sample having likely been dug after 1895: there are 3 brick wells dating to the last quarter of the century. It thus illustrates that while piped water was being introduced in urban areas at this time, many rural areas did not receive plumbing until the 1930s.

5.5 Excavation Approaches

The wells in the sample were archaeologically excavated through a mix of hand and mechanical excavation methods. For obvious reasons, the deeper the excavation, the more likely a backhoe or other machine was used. Table 5.15 gives the minimum, maximum and average depths in feet of archaeological well excavations by method. Additional aids appear to be uncommon. Excavation at Thompson's Loss and Gain Feature 78 used corrugated metal well casing as shoring to remove barrel staves, but no other report mentioned using shoring. Stepping or sloping excavation to ensure safety appears to have been more common. A one-inch diameter pump was used during excavation of the wells at the Jones site, but review of the other reports did not indicate whether dewatering was done on other sites. As was said before, most well excavations ended when the water table was reached.

	min	max	av
Hand excavation	0.5	13.5	7.1
Hand and mechanical	6.7	30.0	13.2
Mechanical	10.0	14.0	12.0

Because wells in Delaware are relatively shallow, these methods appear to be generally adequate, with the exception of not always recording the bottom depth of a well. In many

cases, the addition of dewatering would likely have allowed mechanical excavation the few more feet below the water table necessary to document the bottom of the well, and obtain a sample of artifacts. In the case of deeper wells (there were two wells 25 feet or more deep), perhaps boring or auguring might be considered if stepping or shoring to support safe excavation to the required depth is prohibitively expensive. This might well require geotechnical boring to get through the bottom of the well and any debris present. The bottom depth of the well should be apparent in a geotechnical bore, but a sample of potentially datable artifacts indicating the time period of abandonment would not be recovered.

6.0 MANAGEMENT RECOMMENDATIONS

6.1 Methodological, Analytical and Substantive Gaps

Analysis of wells excavated in Delaware reveals a number of interesting patterns about these simple but vital features of the landscape. Wells in Delaware were nearly always very shallow (most less than 15 feet deep) and made with a variety of materials and construction techniques. We have wells made from brick, stone and stone and brick together. Wood-lined wells were mostly rectangular frame in construction, but could also be circular, or made with stacked barrels, and in one case, stacked hollow logs. Most of these technologies appear to have been used throughout most of Delaware's history, though the range of wood-lined wells (last quarter 17th century to 3rd quarter 19th century) is a little earlier than brick-lined wells (2nd quarter 18th century to the present). Brick and wood wells are found in each of the three counties of Delaware, but stone-lined wells are found only in the northern part of New Castle County, the only part of the state in the Piedmont where stone is more common, rather than in the Atlantic Coastal Plain.

Nearly all of the wells in the excavated sample were found very close to a structure (within an average of 25 feet). There were differences within the sample in the well-lining material and the type of nearest structure. Stone wells were more likely to be associated with a dwelling or other principal structure and wood-lined wells were more likely to be associated with an outbuilding, perhaps because outbuilding wells did not warrant the effort towards permanency given to wells associated with a dwelling. Differences in well material were also found between sites of differing socio-economic class. All of the barrel-lined wells on farms in our sample were found on tenant farm sites. By contrast, most of the stone-lined wells were from owner-occupied sites. This might suggest a higher frequency of expedient well linings like barrels at tenant occupied sites, and a greater frequency of higher cost linings, like stone, at owner occupied sites. But then one would expect more brick-lined wells at owner-occupied sites, with more wood-lined wells at tenant sites, but the opposite is true. One possible explanation for this is that wood-lined wells averaged earlier dates than brick-lined wells (mid to last quarter 18th century vs first to second quarter 19th century), while owner-occupied sites in the sample had an earlier average date than tenant-occupied sites in the sample (3rd quarter 18th century vs 1st quarter 19th century). Thus the pattern with wood-lined and brick-lined wells may have more to do with chronology than ownership status.

These results offer some potentially interesting insights into the use of wells on Delaware sites. But in most cases, the dataset suffers from small size, and some attributes are not completely or consistently recorded. Oftentimes, wells appear to be treated in the archaeological record primarily as receptacles for artifacts, rather than as important features in their own right. Reports of sites containing wells do not always contain detailed descriptions of the construction techniques or materials. The bottom depth is not always recorded, often owing to the difficulty in safely obtaining samples from substantially below the ground surface. Descriptions of well features do not always say clearly whether there is any evidence of a builder's trench that might help date the construction of a well, or evidence of repair episodes. Specific details about brick type

and size are often missing, as is detailed description of wood frame construction techniques. And in interpretation of well features, an estimated range of use is not always given.

More detailed recordation of well features might help flesh out the chronology of well construction, repair, and replacement. Wells, especially those built with impermanent materials like wood framing or barrels, would have needed at least occasional repair or replacement. Examining well shaft features for evidence of repair episodes would help illuminate the level of effort needed to keep these features functioning. Evidence for the use of specialized or unusual materials such as curved or glazed bricks should be particularly noted. Changes in a well, or the digging of a new well can also point to significant changes in a site's occupation, such as a new owner or tenant. For this reason, evidence for the date of abandonment of a well, such as from artifacts found in the well shaft near, but above the water table, are important to record and analyze. Once artifacts begin to accumulate above the water table, clearly the well can no longer be used.

Although most wells in Delaware appear to be relatively shallow, nevertheless, excavation to the bottom of a well below the water table presents significant logistical concerns. It may be possible to measure the bottom depth of a well using a geotechnical bore, thus avoiding the need to fully expose the lowest strata. However, this will not recover any artifacts from the bottom that could be used to date the time of abandonment. The only way to get that information is through controlled excavation to the bottom, likely requiring dewatering techniques. It is not likely to be safe to excavate a well from inside. Even with the insertion of a support structure such as a tube to prevent collapse, such an excavation would present significant hazards associated with confined spaces. Total excavation in stages from outside the well with ample stepping and or shoring of the excavations would be the safest approach.

More thorough excavation of wells should help with more precise dating of their construction and abandonment. Further research into local environmental history may tie a finer well chronology to regional rainfall cycles. A 248-year reconstruction of streamflow in the Potomac River has been generated based on tree-ring evidence (Cook and Jacoby 1983). This reconstruction suggests that since 1730, there have been several long periods of about 50 years in length when the river's flow has been abnormally high or low (Figure 6.1). This study, and other similar studies, note several long periods of apparent drought in the Middle Atlantic United States, such as the one peaking in about 1820, and another from the 1850s through the mid 1860s (Cook and Jacoby 1983; Seager and Herweijer 2011). Periods of prolonged drought could have affected local water tables, causing some shallow wells to fail. Comparison with approximate Delaware well construction dates does show an increase in the number of wells dug during the quarter century from 1850 to 1875, a period of drought. There are two caveats that should accompany this observation: the well construction dates are not very precise, and the impact of noted droughts on Delaware water tables is not known for certain. However, this suggests an interesting avenue for future research. How were Delaware farms affected by changing climatic conditions as reflected in particular farm features like wells?

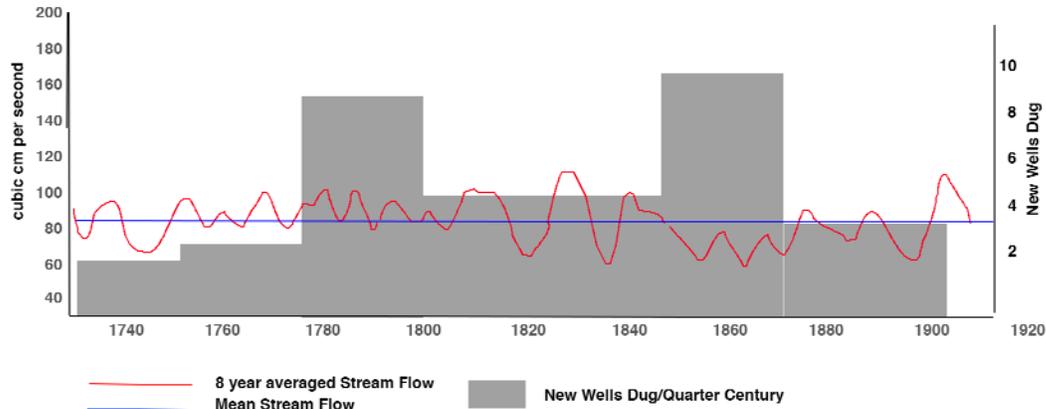

Figure 6.1: Comparison of Reconstructed Streamflow for the Potomac River at Point of Rocks, MD. After Cook and Jacoby (1983) with Delaware well construction.

The research to date suggests that wells were typically dug near site structures, and most often in well drained soils; distance to surface water appears to have been less important. More work could be done to understand how well locations were chosen within sites. Well features are consistently mapped horizontally, but their relation to site microtopography and soil chemistry would be interesting additions to typical recordation. Information on microtopography might provide some insight into the practice of well siting. Information about adjacent soil chemistry might provide some interesting clues about possible water contamination from human or animal waste, or other site activities. Given how shallow wells were in Delaware, water contamination could have been a significant health issue prior to the advent of modern plumbing.

The sample of wells in this study provided an opportunity to examine the rough chronology of different types of well construction. Expanding the sample will allow this chronology to be confirmed or refined, as well as providing the data necessary to further explore possible connections between well type and type of site occupation. Despite the number of wells excavated in Delaware, significant gaps remain. Once the existing sample of excavated wells is divided by construction type, period, and region, the number of similar wells becomes quite small. In particular, the number of wells excavated in the state declines steadily from north to south. The sample of wells from Sussex County is particularly scant. Excavating more wells in Sussex County may help show whether the patterns found here hold throughout the state, or have more to do with the northern part of Delaware.

6.2 Research Priorities

Although the overall problems with sample size and recording inconsistencies provide reasons to record in detail any historic well found on an archaeological site, it is possible to suggest some priorities. Evaluation of the information potential of a well should put emphasis on those with a good historical context. It would be good to explore the possible relationship between well type and ownership/tenancy. To do this, wells of documented occupation are more valuable than wells whose social context is ambiguous.

Similarly, wells that can be securely dated, either through artifact contents, materials used or documentary evidence, are more useful than wells whose use dates are unclear. Ideally, both well construction and abandonment dates are needed, and should be clearly identified if known in the resulting report.

Wells located in sites with overall high physical integrity have more information potential than isolated wells. Wells from sites with evidence for the location of nearby structures, as well as the potential for meaningful soil chemistry will be able to better illustrate how the well feature functioned within the overall site, and potentially how safe the water from that well might have been.

Wells with features related to water extraction technology (such as the pump at the Armstrong Rogers Site) or which have a clear functional association are more valuable than wells that lack functional context. The well at the Armstrong Rogers Site is associated with the dairy, for example. The better the overall site integrity is, the more the well has to say.

The better a well's context, archaeologically and historically, the more valuable the feature. Conversely, wells that are not accompanied by other well-preserved features with clear functions, or that are on sites with little or no documentation, or that cannot be reliably dated, are not necessarily valuable archaeologically. If a site lacks good documentation or well-preserved features other than a well, the presence of even a well preserved well is probably not enough by itself to make the site eligible.

APPENDIX A

WELL DATA

Table A.1: Data from Excavated Wells

ID	Site Number	CRS Number	Site Name	Feature Number	Site Type	County	Hundred	Watershed	NRCS Soil Symbol	NRCS Map Unit Name	Well Lining	Well Shape	Well Setting
55	7NC-F-128	N114508	Cardon/Holton	104	tenant farmstead	New Castle	Saint George's	Appoquinimink River	ReB	Reybold silt loam, 2 to 5 percent slopes	wood box	square	rear/side yard
56	7S-K-118		Laban Rogers House	219	farmstead	Sussex	Baltimore				wood tube	round	rear/side yard
57	7S-K-118		Laban Rogers House	269	farmstead	Sussex	Baltimore				wood box/barrel	square	rear/side yard

Table A.1: Data from Excavated Wells

ID	Site Number	CRS Number	Site Name	Feature Number	Construct Method	Feature Notes	Period of Use	Dates Occupation	Dates Fill
55	7NC-F-128	N114508	Cardon/Holton	104	wood box casing; corner posts with horizontal hard planking and wrought nail fasteners	Upper 4 ft of builders shaft was 12 ft diam. Cylinder shored with wood planks. Box framing began at 4 ft below pz. The wooden posts (probably oak) were hand-hewn with an adze and the ends pointed with an axe. The well sides were fashioned from large logs, split with a froe into wedge-shaped planks (some also with bark).	1737 to after 1753		
56	7S-K-118		Laban Rogers House	219	hollow larch log tubes within hand-exavated shaft	hollowed larch tube (3' long, 2' diam) was placed at center of shaft at the water table allowing soil to be removed from within tube; additional tubes were stacked resulting in a wood lining; Sections of the wood tube were recovered - all larch; 1 eastern white pine board;	1775-1825		
57	7S-K-118		Laban Rogers House	269	wood frame utilizing hewn oak timbers with barrel at the base	builders trench excavated, barrel place at base of excavation providing 2-ft wide, 3-ft deep column for water extraction. Hewn oak posts and split oak clapboards fromed a 3-x-3ft box structure above the barrel for a total of 5 feet from surface to top of barrel. Lack of personal items suggest well was utilized at a livestock or dairy well.	1775-1800		MCD 1805

Table A.1: Data from Excavated Wells

ID	Site Number	CRS Number	Site Name	Feature Number	Dates Builders	Chronology Notes	Nearest Water	Dist to Water (ft)	Dist to House (ft)	House Notes	Dist to Kitchen (ft)
55	7NC-F-128	N114508	Cardon/Holton	104		dendrochronology. A comparison of production dates for the other diagnostic ceramics suggests a date range between 1720 and 1740. Dates of 1737 and 1753 were returned from preliminary dendrochronological analysis.	Unnamed Tributary to Drawyer Creek	2500	90	Possible House Footprint	0
56	7S-K-118		Laban Rogers House	219		Recovered ceramics suggest a late 18th C/E 19th C timeframe for construction and use of well; builders trench and shaft artifact contents were similar suggesting brief use		0	0		0
57	7S-K-118		Laban Rogers House	269	MCD 1774	Recovered ceramics suggest a late 18th C/E 19th C timeframe for construction and use of well; MCD of 1805 for upper portion of shaft; MCD for builders trench and lower shaft is 1774.		0	0		0

9	7K-C-203C	K06033	Richard Whitehart Plantation	495	no lining evident	watertable at 10.75 below surface; conical excavation, tapers from 8 ft at surface to 1 ft at base.		ca. 1681-1701	
10	7K-C-203H	K06033	John Powell Plantation	39	wood box casing; corner posts with mortise and tenon horizontal supports	Cribbing encountered at 5 ft below base of plow zone. The cribbing consisted of four 7-ft long squared timbers set vertically along the outer edge of the well shaft. The timbers measured 0.4 x 0.3 ft and fanned a 2-ft square well shaft. The bottom of the cribbing rested on the bottom edge of the builder's trench at 12.2 ft below subsoil. The next 7 ft of the well shaft was not cribbed. The second set of cribbing was encountered at 19 ft below subsoil. This cribbing consisted of four 2 ft long squared timbers and several fined crosspieces. The four vertical posts rested on the bottom of the well. Each timber was the same size as the upper cribbing. The mortise and tenon supports were also similar in construction; water table depth / inundation not mentioned in report Builders trench identified.	ca. 1691-1721	ca. 1691-1735	1720.2 (pipe stems)

11	7K-C-362	K06385	Benjamin Wynn Tenancy	94	wood box casing; corner posts with horizontal planking; nailed; barrel lining	<p>Seven large posts found in association with well opening were interpreted as 10-x-10 ft well cover or curb.</p> <p>Cribbing was identified at 4.3 ft below subsoil. These remains consisted of the stains of four large, square corner posts set into a 1.5-ft square well shaft. Intact portions of all four hewn posts were encountered at 4.7 ft below subsoil. Also identified at this level were the remains of four large horizontal spindles forming a large box around the four vertical posts. Each of these spindles measured between 2.0 and 2.2 ft in length and extended beyond the vertical posts in a "pinwheel" pattern. The four "pinwheel" spindles were attached to the four vertical posts with hand-wrought nails. These spindles, however, were otherwise very poorly preserved and no other architectural features could be identified. The spindles appeared to be at least four inches wide and less than two inches thick. The "pinwheel" extensions on these spindles probably served to center the well shaft when the builder's trench was back filled.</p> <p>19 horizontal wooden planks between the vertical posts were encountered at 5.8 ft below base of plow zone.</p> <p>Barrel encountered at - 8.1 ft within cribbing.</p>		ca. 1765-1822	MCD range 1762-1825

13	7K-C-375	K06414	Wilson-Lewis Farm	123	excavated well shaft lined with barrel	<p>Not fully excavated; Feature 123, was the first well at the site. The second well, Feature 127, clearly postdated the first well and was probably constructed immediately after Feature 123 as fragments of the same brown glass mucilage or paste bottle (Figure 84) were found in the well shaft of Feature 123 and the builder's trench of Feature 127. Thus, Feature 127 postdates Feature 123 and both may have been open simultaneously for a short period while the later well was being dug. The proximity of both wells also suggests that the second well, Feature 127, was dug for some reason other than insufficient or contaminated water. If the first well went dry or was contaminated, it is unlikely that a second well would have been constructed so close by. The first well, Feature 123, was abandoned and the second well constructed sometime after 1869.</p> <p>The well locations in the front yard and proximity to Lewis Drive makes it unlikely that both features were privies although a series of seven post holes around both wells suggests that they were perhaps covered by a single small structure (10-x-12ft).</p> <p>Shallow water table noted.</p>		ca 1850-1889	MCD 1865.9

ID	Site Number	CRS Number	Site Name	Feature Number	Site Description	Depth to Water Table (ft)
20	7K-C-383	K06443	W. Eager Farmstead	23	The site is a mid to late-19th century tenant-and owner-occupied farm occupied by a succession of relatively poor tenants and landowners. The occupants of the site were sensitive to minute changes in the local economy. The effects of such local economic and social changes are reflected in the material culture of the occupants and changing land use patterns at the site.	3
21	7K-F-154	K00816	Webb's Landing	0	Presumed domestic. No documentation on excavations which were conducted by the Section of Archaeology in 1969. One photograph of well excavation in progress is only record on file at DE SHPO. Artifact collection is curated at DE SHPO.	3

29	7NC-D-130	N10900	Thomas Williams	2	coursed, dry-laid, stretchers, single wythe; wood base and pump stock; ext. lined with barrel staves	Eight barrel staves, measuring 1" to 1.25" in width, were recovered from the excavations. A squared wooden pump stock, about 1.8' in height and .3' square, was found in the center of the well shaft. Consisting of a single wooden piece with horizontal saw marks, the pump stock had four square holes chiseled into the center of the stock, two each on opposite sides of, and slightly offset from the other pair. Beneath the final course of brick, a wooden curb or foot ring was identified. This ring was constructed of two hand-planned thicknesses of timber, about .6' wide, nailed together with cut nails. The wooden ring was connected to the barrel staves, and had a diameter of 4.0', suggesting that the barrel which was used in the construction had probably been a hogshead (54 gal), a puncheon (72 gal), or a butt (108gal); no builders trench identified.		ca. 1792-1920s	MCD 1810
30	7NC-D-203	N13542	Springer/Ward/Little Farm	918	upper portion-mortared and dressed fieldstone; lower dry-laid fieldstone	The northern portion of the well was dis-mantled revealing a layer of ash/cinder, mucky loam, and the water table at 12 foot below surface. The lower part of the well was lined with quartz rocks and the cap consisted of Wissahickon schist.		ca. 1850-1930

Table A.1: Data from Excavated Wells

ID	Site Number	CRS Number	Site Name	Feature Number	Site Description	Depth to Water Table (ft)
29	7NC-D-130	N10900	Thomas Williams	2	Historic research found that the site was successively occupied by a tenant farmer (1792-1846), a stone mason (1846-1875) and a black laborer (1887- 1920s). Archaeological remains were found to be associated with all three of the periods, with the tenant farmer and black laborer occupations the best archaeologically represented.	4
30	7NC-D-203	N13542	Springer/Ward/Little Farm	918	The site is a small Piedmont farm established by the Springer family before 1796. Between 1850 and 1860, the farm's value greatly increased, and it remained a successful operation into the 20th century. Archaeological investigations showed that the extant stone ruins of a barn, other buildings, farmhouse and springhouse all date to the period of improvement after 1850.	38

41	7NC-F-139	N14517	Houston-LeCompt	697	wood box casing; corner posts with horizontal planking; wooden pegs	Circular in shape, the diameter measured 6.56 ft with a 2.95-ft protrusion on the southern half. Constructed of white oak corner posts that were cleaved and pinned, the well frame contained a 4-in thick wood base slab functioning as a filter to help keep sandy soil out of the water. Lime, found all around the well, was used to help purify the deposits.		1790s-1840s	1795 mcd
42	7NC-F-139	N14517	Houston-LeCompt	687	coursed, dry-laid, stretchers, single wythe; hand-made brick; barrel base	An old yellow pine wood barrel was used as the base of the well shaft in lieu of a box frame, and the upper shaft was formed of hand-made brick salvaged from the original Houston house cellar. When the later dwelling was demolished in the 1930s, occupants used the well for architectural refuse. Pressed roofing tin, cut stone, and other materials packed the upper stratum, preserving the well remains below and providing information on the second dwelling on the site.		1840s-1930s	1880

49	7NC-J-204	N12898	Jones	156	Historical research suggests there were two periods of occupation by unknown tenants between 1760 and 1820, and again from the mid-19th-century into the 20th-century. The site may have been abandoned for a period of 20 or 30 years. Major features of the Jones Site included a late 18th-century or early 19th-century brick clamp and associated mixing pit for preparing the clay, plus postholes for a probable canopy/shed structure to shelter the brick-molders. Additional features included a barrel-lined well from the same occupation period; a brick-lined well and terra cotta drain lines dating from the late 18th through early 20th centuries; and pits and fencelines of uncertain date. The artifact assemblage comprised primarily brick fragments and wasters; there were relatively few domestic artifacts, and many of those were very small. The absence of a clear dwelling foundation and the sparse artifact assemblage suggests the site was a working area of a farm, possibly with outbuildings, but not the location of a dwelling.	9

Table A.1: Data from Excavated Wells

ID	Site Number	CRS Number	Site Name	Feature Number	Site Description	Depth to Water Table (ft)
50	7NC-J-204	N12898	Jones	268	<p>Historical research suggests there were two periods of occupation by unknown tenants between 1760 and 1820, and again from the mid-19th-century into the 20th-century. The site may have been abandoned for a period of 20 or 30 years. Major features of the Jones Site included a late 18th-century or early 19th-century brick clamp and associated mixing pit for preparing the clay, plus postholes for a probable canopy/shed structure to shelter the brick-molders. Additional features included a barrel-lined well from the same occupation period; a brick-lined well and terra cotta drain lines dating from the late 18th through early 20th centuries; and pits and fencelines of uncertain date. The artifact assemblage comprised primarily brick fragments and wasters; there were relatively few domestic artifacts, and many of those were very small. The absence of a clear dwelling foundation and the sparse artifact assemblage suggests the site was a working area of a farm, possibly with outbuildings, but not the location of a dwelling.</p>	9

52	7S-G-57	S00717	Avery's Rest	11	wood box casing; mortise and tenon frame with pinned tenons and vertical planks between corner posts held in place by builders trench fill; no nails utilized.	Feature 11 appears to be John and Sarah Avery's well (1674-1682) based on artifacts on and near the floor of the feature and below the "Vacancy Period" fill. The well had evidence of two shaft casings, the outer casing, which seems to have been dismantled, was not as deep as the inner casing, the bottom portion of which was preserved below water table. After 1682 the site appears to have been abandoned until the re-occupation by daughter Jemima (Avery) Morgan in 1698. During the vacancy period, the well casing failed and the shaft partially filled in with sediment from soil erosion. The upper levels of the failed well feature were used by the Morgan's for refuse disposal.	ca. 1674-1682	ca. 1674-1715	
53	7S-G-57	S00717	Avery's Rest	7	wood box casing presumed	No intact cribbing; wood fragments are only remain evidence of lining. Interpreted as well of Jemima (Avery) Morgan (1698-1715), based on artifact content.	ca. 1698-1715	ca. 1674-1715

58	7NC-F-64	N10284	Jacob B. Cazier Tenancy			Mr. Biddle reported a well located midway along the east wall of the dwelling, approximately 5-7 feet from the side of the house. The well was filled and eventually covered by the pavement of Route 896. This well served as the only source of water for the Cazier site throughout its entire history.	
59	7NC-E-126	N12918	Horrace Burr House				
60	7K-C-379B	K00394.051	Blue Anchor Tavern				
61	7NC-B-58	N13791	Vandever-O'Neal House		circular	located adjacent to north side of house

Catts, and Rebecca Tinsman, 1994, Status, Landscape, and Tenancy at Mount Vernon Place: Final Archaeological Investigations of the Jacob B. Cazier Tenancy #2, State Route 896, New Castle, Delaware. Delaware Department of Transportation Archaeology Series, No. 104. Delaware Department of Transportation, Dover, Delaware.	L 19th-E 20th century; brick house foundation and cellar and more than 200 features including an addition to the house, privies, outbuildings, and fencelines were excavated.
59	7NC-E-126	N12918	Horrace Burr House		Robert F. Hoffman, Betty C. Zebooker, and Lauren C. Archibald, 1993, Phase I/II Cultural Resources Survey of the Homestead (7NC-E-126, Horace Burr House), Located on a Five-Acre Parcel Fronting on Route 9 South of Wilmington, New Castle County, Delaware. MAAR Associates, Newark, DE. Submitted to Delaware Division of Historical and Cultural Affairs, Dover, DE. Unpublished report on file at SHPO, 15 The Green, Dover, DE.	The investigations involved historical documentation of the property, and an architectural evaluation of a mid-to-late nineteenth century country residence located in the project area, as well as archeological testing of the five-acre parcel to locate and evaluate previously recorded and/or documented sites, and to locate new resources.
60	7K-C-379B	K00394.051	Blue Anchor Tavern		Edward F. Heite, 1990, Archaeological Investigations at the Blue Anchor Tavern, 2 Volumes. MAAR Associates, Inc., Newark, DE. Submitted to Dover Parking Authority, Dover, DE. Unpublished report on file at DESHPO, 15 The Green, Dover, DE.	The Blue Anchor Tavern lot excavation contains a number of features associated with everyday life in early Dover. Dog burials, garden plots, minor outbuildings, wells, all are represented through three centuries. The collection adds many pieces to the jigsaw puzzle of early Dover.
61	7NC-B-58	N13791	Vandever-O'Neal House		Nedda E. Moqtaderi, 2000, Archaeological Testing and Archival Research at the Vandever-O'Neal Site, Mt. Cuba, Greenville, Mill Creek Hundred, Delaware. Unpublished report on file at DESHPO, 15 The Green, Dover, DE.	The archaeological testing and mapping of the extant foundations and features at the Vandever-O'Neal Site provides a physical history of landscape, architecture, and spatial organization on a nineteenth-through early twentieth-century farm

APPENDIX C
PROJECT PERSONNEL

VERSAR PROJECT PERSONNEL

Brian D. Crane, Ph.D., R.P.A., Project Manager

B.A., 1986, Anthropology, University of Pennsylvania, Philadelphia, Pennsylvania

M.A., 1987, American Civilization, University of Pennsylvania

Ph.D. 1993, American Civilization, Historical Archaeology, University of Pennsylvania

Years of Experience: 20

Dr. Crane is a Senior Project Manager and the Cultural Resources Division Director of Versar. He served as the Project Manager for this project. Dr. Crane has over 20 years of experience in all phases of historic and prehistoric archaeological projects in the United States, Caribbean and Central America, with academic projects, and projects in compliance with Section 106 of the National Historic Preservation Act of 1966 and other federal, state and local legislation. Responsibilities have included program management, project design and implementation, field and laboratory supervision, artifact analysis, archival research, public outreach, and report writing. Areas of expertise include GIS and cultural resources data management, historical archaeology, urban archaeology, and African American archaeology.

Dennis A. Knepper, Senior Archaeologist

B.A., 1977, History, Texas Christian University, Fort Worth, Texas

Years of Experience: 25

Mr. Knepper is a Senior Archaeologist with Versar and provided GIS and technical writing support for this project. He has 25 years of experience as an archaeologist in Texas, the Southwest and Mid-Atlantic regions of the United States as well as Latin America, the Caribbean, and East Asia. He has directed numerous prehistoric and historical survey, testing, and data recovery projects in compliance with Sections 106 and 110 of the National Historic Preservation Act of 1966, as amended, for regulatory compliance with FHWA, FERC, GSA, USACOE, and other federal and state agencies. Responsibilities have included project design and implementation, field and laboratory supervision, artifact analysis, archival research, database management, predictive modeling, and report writing.

Christopher L. Bowen, Archaeologist

B.S., 1992, Interdisciplinary Studies, Radford University, Virginia

Years of Experience: 20

Mr. Bowen is a Staff Archaeologist with Versar and provided GIS, graphics, and technical writing support for this project. He has 20 years of experience as an archaeologist in the Mid-Atlantic regions of the United States as well as the West and Mid-West. He has conducted numerous prehistoric and historical survey, testing, and data recovery projects in compliance with Sections 106 and 110 of the National Historic Preservation Act of 1966, as amended, for the Air Force, Federal Highway Administration, U.S. Army Corps of Engineers, and other Federal and state agencies.

Wells in Delaware

Responsibilities have included project design and implementation, field and laboratory supervision, artifact analysis, archival research, database management, GIS analysis, and report writing.

Report Authors: Brian Crane, Christopher Bowen, Dennis Knepper

LIST OF TABLES

Table 1: Proposed Historical Wells Data Table Fields..... 2
Table 2: Proposed Project Schedule 4
Table 3: Proposed Project Staffing 5

1.0 INTRODUCTION

The following technical proposal is submitted to the Delaware Department of Transportation (DelDOT) by Versar, Inc. (Versar), under Agreement 1539, Task 6. The proposed work will involve an alternative archaeological mitigation for the Polk Tenant Site (N05221, 7NC-F-111).

Phase I and II field work for the Polk Tenant Site was conducted in April and May of 2011 by Richard Grubb and Associates (Grossman-Bailey at al. 2011). Phase II excavation found that the site was eligible for the National Register of Historic Places (NRHP). Significant features associated with the site included a 19th-century well. However, considering that only a small portion of the site would be physically impacted by Route 301 construction, the site appeared to be a better candidate for alternative mitigation rather than intensive excavation. The presence of an intact well feature at this site and others within the 301 Corridor was the basis for identifying wells as a focus of the alternative mitigation. DelDOT and the Delaware State Historic Preservation Office (DE SHPO) concurred with this recommendation.

2.0 TECHNICAL APPROACH

2.1 Project Management

This task includes project management and direct costs for management activities necessary over the course of the project. Project management activities include project coordination and oversight, budget and schedule management, project kickoff meeting, preparation of Progress Reports, project accounting and billing, and technical direction. Project management also includes the preparation of a monthly update and blog entry to be submitted to David Clarke at DelDOT via email throughout the duration of the project.

2.2 Task 1, Section 106 Report

A management summary of the site testing was prepared by Richard Grubb and Associates (Grossman-Bailey at al. 2011). Versar will expand this management summary into a single technical report, detailing the goals, methods, and results of the project in detail in compliance with Delaware State Historic Preservation Office standards for National Register Evaluation Reports and 36 CFR 800. The report will include: a project introduction; presentation of previous investigations; a site-specific historical context; presentation of the field findings; and discussion and conclusions. The discussion and conclusions will include the NRHP eligibility statement, the reasoning behind the decision to conduct an alternative mitigation, and the technical proposal for alternative mitigation. The document will include detailed site maps and photographs depicting field methodology, stratigraphic profiles, and select artifacts. A complete artifact catalog, including the Phase I and Phase II collections will be included as an appendix. The artifact catalog will be generated by Richard Grubb and Associates, and is not part of this Task. Three bound copies and two compact disks, including PDF and Word versions of the draft report, will be submitted to DelDOT. DelDOT will be responsible for

forwarding the draft report to the DE SHPO for review and concurrence. DelDOT will address all DE SHPO comments to the draft.

2.3 Task 2, Historical Well Synthesis

Versar will conduct a literature review in order to investigate historical wells as an archaeological feature type in Delaware. This review will be conducted from a regional (including urban versus rural) and temporal perspective, and will include interviews with Alice Guerrant at DESHPO and Charles Fithian at the Delaware State Museum. The scope of this effort will be limited to wells as a feature type, though cistern features considered possibly to be wells will also be included. This review will define wells as a feature type; discuss how they were constructed and used; and assess what has been learned from excavation and analysis of these features. The data will be analyzed to determine whether there are taxonomies of well types according to time period and setting, and whether there are temporal or regional patterns of well placement and construction. As part of the literature review, available data pertaining to historical wells previously excavated within Delaware will be collected in order to populate a table listing selected attributes for each well including provenience information, environmental setting, construction methods and materials, pertinent measurements, and archaeological excavation methods employed. Using the data collected, a map indicating the location of all wells listed in the data table will be prepared. Proposed data fields are listed in Table 1. The proposed fields may change slightly in consultation with DelDOT should the research show that some fields are redundant or have no data (e.g. Well Type or Height).

Table 1: Proposed Historical Wells Data Table Fields

Field Name	Description	Data Type
Well ID	unique identifier for each well	text
CRS Number	SHPO number from site files...	
Site Number	state trinomial	text
Site Name	common or local name or other designation	text
Site Type	domestic, industrial, agricultural, etc.	text
Site Description	brief site description/summary	memo
County	county in which site is located	text
Hundred	hundred in which site is located	text
Watershed	watershed in which site is located	text
NRCS Soil Type	NRCS Web Soil Survey soil type for feature area	text
Feature Number	number or other designation used during archaeological investigation	text
Well Type	specific type or taxonomic designation	text
Construction Method	materials used (e.g. brick, stone, wood)	text
Feature Description	brief narrative description of well	memo
Period of Use	date range well was in use	text
Elevation	elevation in feet of well opening above mean sea level	number
Nearest Water	name or description of nearest permanent water source	text

Table 1: Proposed Historical Wells Data Table Fields

Field Name	Description	Data Type
Distance to Water	distance in feet to nearest permanent water source	number
Setting	description of well location within site	memo
Distance to House	distance in feet from well to main domestic structure	number
Distance to Kitchen	distance in feet from well to kitchen	number
Distance to Outbuildings	distance in feet from well to outbuilding, and outbuilding type	text
Excavation Methods	excavation methods used (i.e., hand or mechanical)	text
Excavation Methods Notes	brief narrative of methods or additional information on methods	memo
Excavation Duration	duration of well excavation in man hours	number
Special Analyses	special analyses conducted on well materials (i.e., brick or soil chemistry)	text
Depth	total depth of well in feet	number
Excavated Depth	depth of well as excavated, if not fully excavated (in feet)	number
Diameter Exterior	dimensions of well opening, exterior (<i>n-x-n</i>)	text
Diameter Interior	dimensions of well opening, interior (<i>n-x-n</i>)	text
Height	height in feet of well structure above ground surface	number
Contents	summary of well contents, summarize artifacts if present	memo
Imagery	photograph(s) or drawing(s) of well	image file
References	report reference	text

Analysis of the data collected for the table will seek to identify patterns relating to well type, function, setting, and contents by period and geographical area. Research questions to be explored through this synthesis include:

- Does well construction vary with time period or region?
- Is there a taxonomy of wells beyond construction type (e.g. barrel vs brick)?
- Does well function or location vary with time period or region?
- How does the well at the Polk site fit into the broader context of well types suggested by the synthesis?

The discussion portion of the historical well context will include an assessment of what has been learned through the archaeological excavation of wells from sites in Delaware and an appraisal of the methodologies employed. The goal of the assessment will be to provide recommendations regarding the cost-effectiveness of well excavation in a Section 106 context by well type and setting. Consideration will be given to apparent data gaps as well as areas where data appear to be redundant. Issues regarding well excavation safety, if available in the data, also will be discussed. Sections of the report for the well synthesis will include:

1. Introduction/Definition of the problem
2. Methods
3. Tabular Results
4. Research Conclusions

5. Management Recommendations

2.4 Task 3, Websites

Website 1 will focus on the evolution of Delaware wells, drawing on the results of the literature review and synthesis. This website will include content from the historical well context and 3D digital models of example wells. The models will focus on displaying variation in the construction of wells across time from several sites, including the Avery's Rest site, the Polk Site, the McKean/Cochran Farm Site, and up to two others.

Website 2, will focus on historic standing structures within the Route 301 Corridor. Versar will primarily draw on material and imagery from the A.D. Marble historic structures report to produce individual pages for the website. The house belonging to the owners of the Polk Site will be featured, and historical contexts discussed will include Delaware's peach boom. Imagery will include photographs and maps.

The websites will be designed to anticipate visits of approximately 20-30 minutes and be written at an 8th grade reading level. The well and historic structure websites will be hosted by DelDOT, retain the look and feel of the current DelDOT website, and will use the DelDOT 18th-century kitchen web page as an example. Versar will coordinate with DelDOT on technical requirements and will submit each website on a compact disk. Each page of the individual websites will also be prepared as a PDF file for archival purposes. Two hard copies of the PDF file will be submitted.

3.0 SCHEDULE

Because of the complexity of this project and the need to incorporate the findings of multiple outside efforts, Versar understands that Task 6 may extend to as much as 18 months.

Table 2: Proposed Project Schedule

Month(s) from NTP	Tasks to Perform
months 1-4	Section 106 Report
months 1-4	Literature Review
months 4-8	Data Collection/Entry
months 8-12	Analysis and report generation
month 13	Well Website
month 14	Architecture website

4.0 STAFFING

Key personnel for the project include the Project Director, Principal Investigator, and Field Director. These personnel will be the primary supervisory staff assigned to the project, and they will be supported by individuals drawn from throughout Versar's

Cultural Resources staff (Table 3). The key supervisory staff meet or exceed the Professional Qualification Standards outlined in the *Secretary of the Interior's Standards and Guidelines for Archeology and Historic Preservation* (48 FR 44738-9), as published in the Code of Federal Regulations, 36 CFR Part 61. Proposed project personnel have extensive prior experience in the archaeology of the Middle Atlantic region and participated directly in the fieldwork for the three phase II site evaluations.

Table 3: Proposed Project Staffing

Project Role	Proposed Versar Personnel
Project Director	Brian Crane
Principal Investigator	Mackenzie Caldwell Rohm
Historian	Eric Griffiths
Archaeologist II/Senior Archaeologist	Dennis Knepper
Archaeologist I/ GIS/CADD/Graphics	Chris Bowen

5.0 BASIS OF ESTIMATE

- Versar will not develop an artifact catalog for the Phase II Section 106 report, or perform curation related tasks.
- There will not be more than 75 wells to investigate for the historical well data table. This number assumes that there are approximately 60 wells that have been excavated as part of DEDOT projects in the state, and that non DelDOT projects have excavated approximately 15 others. A sample of 75 wells will cover the large majority of all wells excavated in the state, and will include a representative sample geographically and temporally.
- The effort for the well synthesis will focus largely on identifying excavated wells, and entering key data into the database. These data will be analyzed for patterns important to the interpretation of the feature type, and for the management of wells as a resource, but the write-up of this research will be limited to a chapter of approximately 30 pages.
- There will not be more than 16 separate website pages.
- Versar will provide text and graphical content for the websites, but will not perform website development.
- Versar will develop models of up to 5 wells.
